Recently, studies of bright circularly polarized high-harmonic beams from atoms in the soft X-ray region as a source for X-ray magnetic circular dichroism measurement in a tabletop-scale setup have received considerable attention. In this paper, we address the problem with molecular targets and perform a detailed quantum study of H_2^+ , CO, and N₂ molecules in bichromatic counter-rotating circularly polarized laser fields where we adopt wavelengths (1300 nm and 790 nm) and intensities (2×10^{14} W/cm²) reported in a recent experiment [Proc. Natl. Acad. Sci. U.S.A. 595 **112**, 14206 (2015)]. Our treatment of multiphoton processes in homonuclear and heteronuclear diatomic molecules is nonperturbative and based on the time-dependent density functional theory for multiploarized harmonics with high-energy photons in the XUV and soft X-ray range. Our results reveal intriguing and substantially different nonlinear optical responses for homonuclear and heteronuclear diatomic molecules subject to circularly polarized intense laser fields. We study in detail the below- and above-threshold harmonic regions and analyze the ellipticity and phase of the generated harmonic peaks.

I. INTRODUCTION

High-order-harmonic generation (HHG) is an attractive table-top source of coherent, bright, and tunable sextreme ultraviolet (XUV) and soft X-ray radiation with applications in coherent diffractive imaging, ultrafast holography, and time resolved measurements [1–6]. Moreover, circularly polarized HHG may find additional pplications in nanolithography, ultrafast spin dynamics, and magnetic circular dichroism [1, 7–13].

However, until recently bright HHG was limited to lin-19 ear polarization due to the difficulty of controlling ellip-20 tically and circularly polarized harmonics and their effi-21 ciency. When an atom or molecule is driven by a laser 22 field with slightly elliptical polarization, the electron has 23 some probability of re-colliding with its parent ion it was 24 initially released from, and this results in the generation 25 of harmonics with slight elliptical polarization. However, 26 the HHG efficiency drops drastically with increasing el-27 lipticity of the driving field compared to the case of lin-28 early polarized harmonics generated from linearly polar-29 ized laser radiation [14, 15]. In contrast, for circularly po-30 larized driving lasers, the probability of re-collision and $_{60}$ 31 the emission of high harmonics is completely suppressed. 32 A direct approach for generating circularly polarized 33 ³⁴ HHG was suggested 22 years ago [16, 17], and recently ³⁵ measured by Fleischer *et al.* [7]. In this scheme, circu-³⁶ larly polarized HHG are driven by co-propagating circu-³⁷ larly polarized bichromatic fields that rotate in opposite

³⁸ directions (counter-rotating) and interact with argon gas. ³⁹ This experiment [7] opened up the possibility and motiva-⁴⁰ tion of generating bright circularly polarized HHG comparable to the flux efficiency of linearly polarized HHG. 41 ⁴² Recently, Fan *et al.* [1] did just that, they generated ⁴³ bright circularly polarized soft X-ray HHG beams with ⁴⁴ photon energies greater than 160 eV and flux compara-⁴⁵ ble to the HHG flux obtained using linearly polarized ⁴⁶ 800 nm driving lasers. These bright circularly polarized ⁴⁷ high-order-harmonic beams in the soft X-ray region were ⁴⁸ generated from He, Ne, and Ar atoms, and used to imple-⁴⁹ ment X-ray magnetic circular dichroism measurements in ⁵⁰ a tabletop-scale setup [1]. Previously, such radiation has ⁵¹ only been available at large-scale X-ray facilities such as 52 synchrotrons.

⁵³ Bright circularly polarized soft X-ray high-order-⁵⁴ harmonic beams generated by atomic gases have been ⁵⁵ used in recent experimental studies to probe magnetic ⁵⁶ materials, such as the M-shell absorption edges of Co ⁵⁷ [12], and N_{4,5} absorption edges of Gd [1]. The experi-⁵⁸ ments validated the high degree of circularity, brightness, ⁵⁹ and stability of this light source [1, 12].

⁶⁰ While an impressive progress has been achieved in gen-⁶¹ eration of bright circularly polarized XUV and soft X-ray ⁶² radiation by atomic targets, this area remains largely un-⁶³ explored for molecular systems. In this work, we show ⁶⁴ that generation of bright XUV and soft X-ray radia-⁶⁵ tion with circular polarization is also possible in diatomic ⁶⁶ molecules. We perform an *all-electron* nonperturbative ⁶⁷ investigation of multiphoton processes of homonuclear ⁶⁸ (H₂⁺ and N₂) and heteronuclear (CO) diatomic molecules ⁶⁹ in bichromatic counter-rotating circularly polarized in-⁷⁰ tense laser fields. The H₂⁺ molecule is the simplest two-

²Department of Physics, St. Petersburg State University,

⁷¹ center one-electron quantum system and is used in our ¹²¹ follows:

current study as a prototype diatomic molecule to show 72 clearly the physical effects in the generation of circularly 73 polarized harmonics. Then we proceed and take a look at 74 $_{75}$ many-electron homonuclear (N₂) and heteronuclear (CO) ⁷⁶ diatomic molecules. The H₂⁺, CO, and N₂ molecules all ¹²² (the summation includes all spin orbitals with the same 78 ergies exceeding 160 eV. We also find qualitatively differ- 124 be written in the following general form ⁷⁹ ent nonlinear optical response behaviors for homonuclear ⁸⁰ and heteronuclear diatomic molecules subject to circu-81 larly polarized intense laser fields.

The organization of this paper is as follows. In Sec. II 82 we briefly describe the time-dependent density func-83 tional (TDDFT) formalism for the general treatment of 84 the multiphoton dynamics of heteronuclear and homonu-85 clear diatomic molecular systems subject to bichromatic ⁸⁷ counter-rotating circularly polarized intense laser fields. ⁸⁸ In Sec. III we explore the multiphoton ionization dynam-⁸⁹ ics of H_2^+ , CO and N_2 molecules in detail and describe ⁹⁰ the difference of the ionization process between homonu- $_{^{91}}$ clear and heteronuclear diatomic molecules. In Sec. IV $_{^{128}}v_{\mathrm{ext}}(r,t)$ is the "external" potential due to the interacwe study HHG of H_2^+ , CO and N_2 molecules driven 92 by bichromatic counter-rotating circularly polarized laser 93 pulses. The HHG spectra for all three molecular systems 94 exhibit a distinct doublet structure, and the harmonics 95 within each doublet possess circular polarizations with 96 opposite handedness. In Sec. V we provide a proof of 97 perfect circular polarization and opposite handedness of 98 the harmonics within the doublets, by calculating their 100 ellipticity and phase parameters from the dipole acceler-¹⁰¹ ation data for below- and above-threshold HHG regions. ¹⁰² Section VI contains concluding remarks.

TIME-DEPENDENT NONPERTURBATIVE II. 103 TREATMENT OF DIATOMIC MOLECULES IN 104 BICHROMATIC CIRCULARLY POLARIZED 105 106 LASER PULSES

Detailed numerical procedures we used for the calcu-107 ¹⁰⁸ lation of the H_2^+ molecule can be found in Refs. [18– ¹⁰⁹ 22]. Also, a more in-depth numerical procedure for 110 the TDDFT of diatomic molecules can be found in ¹¹¹ Refs. [5, 23–28]. The basic equations of TDDFT are the ¹¹² time-dependent one-electron Kohn-Sham equations [29] ¹⁴⁴ When these potentials, determined by the time-¹¹³ for spin orbitals $\psi_{i\sigma}(\mathbf{r},t)$ which involve an effective po-¹⁴⁵ independent ground-state density functional theory ¹¹⁴ tential $v_{\text{eff},\sigma}(\mathbf{r},t)$ (atomic units $\hbar = m = e = 1$ are used ¹⁴⁶ (DFT), are used along with TDDFT in the electronic ¹¹⁵ unless stated otherwise),

$$i\frac{\partial}{\partial t}\psi_{i\sigma}(\boldsymbol{r},t) = \left[-\frac{1}{2}\nabla^2 + v_{\text{eff},\sigma}(\boldsymbol{r},t)\right]\psi_{i\sigma}(\boldsymbol{r},t), \qquad (1)$$
$$i = 1, 2, ..., N_{\sigma},$$

¹¹⁶ where $N_{\sigma} (= N_{\uparrow} \text{ or } N_{\downarrow})$ is the total number of electrons $_{117}$ for a given spin $\sigma,$ and the total number of electrons in ¹¹⁸ the system is $N = \sum_{\sigma} N_{\sigma}$. The time-dependent effective ¹¹⁹ potential $v_{\text{eff},\sigma}(\boldsymbol{r},t)$ is a functional of the electron spin-¹²⁰ densities $\rho_{\sigma}(\mathbf{r},t)$ which are related to the spin orbitals as

$$\rho_{\sigma}(\boldsymbol{r},t) = \sum_{i=1}^{N_{\sigma}} |\psi_{i\sigma}(\boldsymbol{r},t)|^2, \qquad (2)$$

 π generate circularly polarized harmonics with photon en- 123 spin). The effective potential $v_{\text{eff},\sigma}(\mathbf{r},t)$ in Eq. (1) can

$$v_{\text{eff},\sigma}(\boldsymbol{r},t) = v_{\text{H}}(\boldsymbol{r},t) + v_{\text{ext}}(\boldsymbol{r},t) + v_{\text{xc},\sigma}(\boldsymbol{r},t), \qquad (3)$$

125 where

$$v_{\rm H}(\boldsymbol{r},t) = \int \frac{\rho(\boldsymbol{r}',t)}{|\boldsymbol{r}-\boldsymbol{r}'|} d\boldsymbol{r}', \qquad (4)$$

¹²⁶ is the Hartree potential due to electron-electron Coulomb ¹²⁷ interaction and $\rho(\mathbf{r}, t)$ is the total electron density,

$$\rho(\mathbf{r},t) = \sum_{\sigma} \rho_{\sigma}(\mathbf{r},t).$$
(5)

129 tion of the electron with the external laser fields and the 130 nuclei. In the case of homonuclear or heteronuclear di-¹³¹ atomic molecules in bichromatic laser fields, we have

$$v_{\text{ext}}(\boldsymbol{r},t) = v_n(\boldsymbol{r}) + (\boldsymbol{E}_1(t) + \boldsymbol{E}_2(t)) \cdot \boldsymbol{r}, \qquad (6)$$

132 where $v_n(\mathbf{r})$ is the nuclear potential,

$$v_n(\mathbf{r}) = -\frac{Z_1}{|\mathbf{R}_1 - \mathbf{r}|} - \frac{Z_2}{|\mathbf{R}_2 - \mathbf{r}|},$$
 (7)

¹³³ with Z_1 and Z_2 being the electric charges of the two nu-134 clei and R_1 and R_2 being their coordinates at the fixed $_{135}$ equilibrium positions. The internuclear separation R is ¹³⁶ equal to $|\mathbf{R}_2 - \mathbf{R}_1|$. The laser electric field strengths $\mathbf{E}_1(t)$ 137 and $E_2(t)$ refer to the two frequency components of the ¹³⁸ bichromatic field. We assume that the laser fields $E_1(t)$ 139 and $E_2(t)$ are polarized in the x-y plane with the molec-¹⁴⁰ ular axis directed along the z axis. Finally, $v_{\text{xc},\sigma}(\mathbf{r},t)$ is ¹⁴¹ the time-dependent exchange-correlation (xc) potential. Since the exact form of $v_{xc,\sigma}(\mathbf{r},t)$ is unknown, the *adia*-142 ¹⁴³ batic approximation is often used [23–27, 30]

$$v_{\mathrm{xc},\sigma}(\boldsymbol{r},t) = v_{\mathrm{xc},\sigma}[\rho_{\sigma}]|_{\rho_{\sigma}=\rho_{\sigma}(\boldsymbol{r},t)}.$$
(8)

147 structure calculations, both inner shell and excited states ¹⁴⁸ can be calculated rather accurately [31]. In this work, we ¹⁴⁹ utilize the improved van Leeuwen-Baerends LB α xc po-¹⁵⁰ tential [32]. The LB α contains two empirical parameters $_{151} \alpha$ and β and has the following explicit form, in the adia-152 batic approximation,

$$v_{\mathrm{xc},\sigma}^{\mathrm{LB}\alpha}(\boldsymbol{r},t) = \alpha v_{\mathrm{x},\sigma}^{\mathrm{LSDA}}(\boldsymbol{r},t) + v_{\mathrm{c},\sigma}^{\mathrm{LSDA}}(\boldsymbol{r},t) - \frac{\beta x_{\sigma}^{2}(\boldsymbol{r},t)\rho_{\sigma}^{1/3}(\boldsymbol{r},t)}{1+3\beta x_{\sigma}(\boldsymbol{r},t)\ln\{x_{\sigma}(\boldsymbol{r},t)+[x_{\sigma}^{2}(\boldsymbol{r},t)+1]^{1/2}\}}.$$
(9)

¹⁵³ Here, ρ_{σ} is the electron density with spin σ , and we 154 use $\alpha = 1.19$ and $\beta = 0.01$ [24–27]. The first two 155 terms in Eq. (9), $v_{x,\sigma}^{\text{LSDA}}$ and $v_{c,\sigma}^{\text{LSDA}}$ are the LSDA 156 exchange and correlation potentials that do not have 157 the correct Coulombic asymptotic behavior. The last ¹⁵⁸ term in Eq. (9) is the nonlocal gradient correction with ¹⁵⁹ $x_{\sigma}(\mathbf{r}) = |\nabla \rho_{\sigma}(\mathbf{r})| / \rho_{\sigma}^{4/3}(\mathbf{r})$, which ensures the proper ¹⁶⁰ long-range Coulombic asymptotic potential $v_{\mathrm{xc},\sigma}^{\mathrm{LB}\alpha} \rightarrow$ $_{161} - 1/r$ as $r \to \infty$. Note that if the conventional xc energy 162 functional forms taken from local spin density approx-¹⁶³ imation (LSDA) or generalized gradient approximation ¹⁶⁴ (GGA) [33, 34] are used, the corresponding xc potential $v_{\rm xc,\sigma}(\mathbf{r},t)$ will not possess the correct long-range asymptotic (-1/r) behavior [35]. For the time-independent $_{167}$ case, this exchange-correlation ${\rm LB}\alpha$ potential has been 168 found to be reliable for atomic and molecular DFT calculations [2, 24–27, 32, 36–38]. 169

In what follows, we shall assume that the molecular axis is fixed in space and directed along the Cartesian zaxis. The laser fields propagate along the z-axis and have circular polarizations in the x - y plane. The countertration fields $E_1(t)$ and $E_2(t)$ are expressed as follows:

$$E_1(t) = \frac{1}{\sqrt{2}} F_1(t) \left[\hat{e}_x \cos(\omega_1 t) + \hat{e}_y \sin(\omega_1 t) \right], \quad (10)$$

175

$$\boldsymbol{E}_{2}(t) = \frac{1}{\sqrt{2}} F_{2}(t - \Delta\tau) \left[\hat{\boldsymbol{e}}_{x} \cos(\omega_{2}t - \Delta\tau) - \hat{\boldsymbol{e}}_{y} \sin(\omega_{2}t - \Delta\tau) \right].$$
(11)

¹⁷⁶ $\Delta \tau$ presents the time delay between the two pulses, $E_1(t)$ ¹⁷⁷ and $E_2(t)$. Since the dipole approximation is well justi-¹⁷⁸ fied in the near infrared wavelength region, the fields are ¹⁷⁹ assumed uniform in space. In Eqs. (10) and (11), ω_1 and ¹⁸⁰ ω_2 denote the carrier frequencies while $F_1(t)$ and $F_2(t)$ ¹⁸¹ represent the temporal pulse envelopes, We use the sine-¹⁸² squared pulse shape:

 $F_1(t) = F_0 \sin^2 \frac{\pi t}{N_1 T_1},$

183

$$F_2(t) = F_0 \sin^2 \frac{\pi t}{N_2 T_2},\tag{13}$$

¹⁸⁴ where F_0 is the peak electric field strength (we use the ¹⁸⁵ same peak field strength for both fields), T_1 and T_2 are ¹⁸⁶ the optical cycle durations for each field $[T_1 = 2\pi/\omega_1]$ and ¹⁸⁷ $T_2 = 2\pi/\omega_2]$, and the integer numbers N_1 and N_2 are the ¹⁸⁸ total pulse durations measured in optical cycles.

Solution of the time-dependent Schrödinger (H₂⁺) and one-electron Kohn-Sham (N₂ and CO) equations for two-center systems is greatly facilitated in the prolate spheroidal coordinates. The relationship between the prolate spheroidal coordinates ξ , η , φ and Cartesian coordinates x, y, z is as follows:

$$x = \frac{1}{2}R\sqrt{(\xi^2 - 1)(1 - \eta^2)}\cos\varphi,$$
 (14)

FIG. 1. (Color online) Time-dependent electric field of the driving laser pulse. The red dotted and blue dashed lines represent the electric field in the x and y direction, respectively. The laser pulse has a duration of 21 optical cycles (~ 55 fs) for the ω_1 (790 nm) component and 8 optical cycles (~ 35 fs) for the ω_2 (1300 nm) component. The time delay $\Delta \tau \sim 11$ fs. Both frequency components have the same peak field strength corresponding to the intensity of 2×10^{14} W/cm².

195

196

1

$$y = \frac{1}{2}R\sqrt{(\xi^2 - 1)(1 - \eta^2)}\sin\varphi,$$
 (15)

$$z = \frac{1}{2}R\xi\eta,\tag{16}$$

¹⁹⁷ where R is the internuclear distance. The dipole inter-¹⁹⁸ action potentials in the length gauge have the following ¹⁹⁹ expressions in the prolate spheroidal coordinates:

$$\boldsymbol{E}_{1}(t) \cdot \boldsymbol{r} = \frac{R}{2\sqrt{2}} F_{1}(t) \sqrt{(\xi^{2} - 1)(1 - \eta^{2})} \left[\cos\phi \cdot \cos(\omega_{1}t) + \sin\phi \cdot \sin(\omega_{1}t)\right],$$
(17)

 $(12)^{-2}$

$$\boldsymbol{E}_{2}(t) \cdot \boldsymbol{r} = \frac{R}{2\sqrt{2}} F_{2}(t - \Delta\tau) \sqrt{(\xi^{2} - 1)(1 - \eta^{2})} \times \left[\cos\phi \cdot \cos(\omega_{2}t - \Delta\tau) - \sin\phi \cdot \sin(\omega_{2}t - \Delta\tau)\right].$$
(18)

²⁰² In Eqs. (10)-(18), $F_1(t)$ and $F_2(t)$ denote the laser pulse ²⁰³ envelope functions, ω_1 and ω_2 are the carrier frequencies. ²⁰⁴ Here, for the counter-rotating circularly polarized pulses, ²⁰⁵ left-helicity corresponds to 790 nm pulse $[\mathbf{E}_1(t)]$ and ²⁰⁶ right-helicity corresponds to the 1300 nm pulse $[\mathbf{E}_2(t)]$. ²⁰⁷ In our calculations, we use the carrier wavelengths ²⁰⁸ 790 nm for the field $\mathbf{E}_1(t)$ ($\omega_1 = 0.0576 \text{ a.u.} = 1.57 \text{ eV}$) ²⁰⁹ and 1300 nm for the field $\mathbf{E}_2(t)$ ($\omega_2 = 0.0350 \text{ a.u.} =$ ²¹⁰ 0.95 eV), respectively. The peak field strength F_0 cor-²¹¹ responds to the intensity $2 \times 10^{14} \text{ W/cm}^2$. The pulse ²¹² durations are chosen as $N_1 = 21$ and $N_2 = 8$, and the ²¹³ time delay $\Delta \tau \sim 11$ fs, which makes $\mathbf{E}_1(t)$ and $\mathbf{E}_2(t)$ ²¹⁴ symmetric about their common center (see Fig. 1). To

²¹⁵ discretize the 3D wave function in coordinate space and ²⁵⁶ 216 propagate it in time, we apply the time-dependent gener- 257 ²¹⁷ alized pseudospectral method (TDGPS) [39]. The time-258 ²¹⁸ dependent Schrödinger (for the H⁺₂ molecule) and Kohn-²¹⁹ Sham (for N₂ and CO molecules) equations are solved ²⁵⁹ The ground-state electronic configurations ²²⁰ by means of the second-order split-operator technique in ²⁶⁰ $1\sigma_g^1$ for H⁺₂, $1\sigma_g^2 1\sigma_u^2 2\sigma_g^2 2\sigma_u^2 1\pi_u^4 3\sigma_g^2$ for N₂ ²²¹ prolate spheroidal coordinates and in the energy repre-²⁶¹ $1\sigma^2 2\sigma^2 3\sigma^2 4\sigma^2 1\pi^4 5\sigma^2$ for CO, respectively. ²²² sentation. To obtain fairly converged HHG spectra for ₂₆₂ highest occupied molecular orbital (HOMO) for H⁺₂, N₂, ²²³ the laser field parameters used in the calculations, we set $_{263}$ and CO is $1\sigma_g$, $3\sigma_g$, and 5σ , respectively. N₂ and CO 224 the grid size (for ξ , η , and φ coordinates, respectively) 264 are isoelectronic molecules, both having 14 electrons $_{225}$ to $96 \times 32 \times 16$ and use 4096 time steps per optical cy- $_{265}$ and triple bonds. Since the CO molecule has unequal 226 cle in the time propagation process. The linear dimen- 266 nuclear charges, its ground electronic state possesses a 227 228 229 apply an absorber which smoothly brings down the prop- 269 Debye [40]. Furthermore, there is no concept of gerade 230 agated wave functions without spurious reflections from 270 and ungerade orbitals for CO (or any other heteronuclear 232 is well described for the laser field parameters used in 272 potential is broken. An important difference between $_{233}$ the calculations, although some very long trajectories (in $_{273}$ the H_2^+ and N_2 and CO spectra is that the latter contain ²³⁴ the semiclassical picture of HHG) may be missing. Of ₂₇₄ even as well as odd harmonics [5, 24–27]. Generation of 235 course, a larger box size is better but it also requires a 275 even harmonics is forbidden in systems with inversion 236 larger number of grid points to maintain the same ac-²³⁷ curacy level of the computed orbitals in the core spatial ²³⁸ region, which is emphasized when calculating the HHG spectra in the acceleration form. The total linear dimension of the propagator matrix for the current grid is 240 49152, which is already very large, and its substantial 241 increase would make the computations impractical. 242

The HHG power spectra can be investigated accurately 243 ²⁴⁴ once the time-dependent Kohn-Sham orbitals and total 245 electron density $\rho(\mathbf{r},t)$ are available. We calculate the ²⁴⁶ expectation values of the induced dipole acceleration in ²⁸³ where $_{247}$ the x, y, and z directions:

248

$$a_x(t) = \int d^3 r \ \rho(\mathbf{r}, t) \frac{\partial v_{\mathbf{n}}}{\partial x} + E_{1x}(t) + E_{2x}(t), \qquad (19)$$

$$a_y(t) = \int d^3r \ \rho(\mathbf{r}, t) \frac{\partial v_{\rm n}}{\partial y} + E_{1y}(t) + E_{2y}(t), \qquad (20)$$

249

$$a_{z}(t) = \int d^{3}r \ \rho(\boldsymbol{r}, t) \frac{\partial v_{\mathrm{n}}}{\partial z}.$$
 (21)

²⁵⁰ Then the power spectra $S(\omega)$ (spectral density of the ²⁵¹ radiation energy) can be obtained by the Fourier trans-²⁵² formation of the time-dependent dipole accelerations,

$$S_x(\omega) = \frac{2}{3\pi c^3} \left| \int_{-\infty}^{\infty} a_x(t) \exp(i\omega t) dt \right|^2, \qquad (22)$$

$$S_y(\omega) = \frac{2}{3\pi c^3} \left| \int_{-\infty}^{\infty} a_y(t) \exp(i\omega t) dt \right|^2, \qquad (23)$$

254

253

$$S_z(\omega) = \frac{2}{3\pi c^3} \left| \int_{-\infty}^{\infty} a_z(t) \exp(i\omega t) dt \right|^2, \qquad (24)$$

$$S_{\text{tot}}(\omega) = S_x(\omega) + S_y(\omega) + S_z(\omega).$$
 (2)

MULTIPHOTON IONIZATION OF H_2^+ , N_2 III. AND CO MOLECULES IN BICHROMATIC CIRCULARLY POLARIZED LASER PULSES

is and The sion of the box where the time-dependent equations are $_{267}$ permanent dipole moment, calculated here to be 0.149 solved is chosen as 43 a.u.; between 23 and 43 a.u. we 268 Debye. The corresponding experimental value is 0.112 the boundary. With this box size, all important physics 271 diatomic molecule) since the inversion symmetry of the 276 symmetry, such as atoms and homonuclear diatomic 277 molecules. This selection rule does not apply to the ²⁷⁸ heteronuclear molecules with no inversion center (CO). 279 Once the time-dependent wave functions and the time-

280 dependent electron densities are obtained, we can calcu-²⁸¹ late the time-dependent (multiphoton) ionization proba-282 bility of an individual spin-orbital according to

$$P_{i,\sigma} = 1 - N_{i,\sigma}(t), \tag{26}$$

$$N_{i,\sigma}(t) = \langle \psi_{i,\sigma}(\xi,\eta,\varphi,t) | \psi_{i,\sigma}(\xi,\eta,\varphi,t) \rangle, \qquad (27)$$

284 is the time-dependent population (survival probability) 285 of the $i\sigma$ -th spin-orbital.

Figure 2 presents the time-dependent population of in-286 ²⁸⁷ dividual spin orbital, as defined in Eq. (27). The slope 288 of the decay of the electron population in time deter-289 mines the ionization rate. The internuclear distance ²⁹⁰ for H_2^+ ($R_e = 2.000a_0$), CO ($R_e = 2.132a_0$), and N_2 $_{291}$ ($R_e = 2.072a_0$) molecules is fixed at its equilibrium dis-²⁹² tance R_e . Results for the counter-rotating laser intensi-²⁹³ ties $(F_0 = 2 \times 10^{14} \text{ W/cm}^2)$ and wavelengths of $\lambda_1 = 790$ ²⁹⁴ nm and $\lambda_2 = 1300$ nm are shown for H₂⁺, N₂ and CO ²⁹⁵ molecules. In Figs. 2(a-c) the laser pulses have a time ²⁹⁶ duration of 21 optical cycles for ω_1 (790 nm) and 8 op-²⁹⁷ tical cycles for ω_2 (1300 nm). The calculated ionization ²⁹⁸ potentials for H_2^+ , CO, and N₂ molecules are 1.1026 a.u. ²⁹⁹ [19], 0.5093 a.u.[5], and 0.5682 a.u.[5], respectively. The ³⁰⁰ multiphoton ionization in the circularly polarized laser ³⁰¹ fields is dominated by the HOMO, that is $1\sigma_q$ in H⁺₂, $_{302}$ 5 σ in CO, and $3\sigma_q$ in N₂. The ionization probability of $_{303}$ H₂⁺ (Fig. 2(a)) is much lower than that of CO (Fig. 2(b)) $_{304}$ and N_2 (Fig. 2(c)), since the H_2^+ molecules ionization $_{305}$ potential is almost twice that of CO and N₂ ionization 306 potentials. The orbital structure and ionization poten-25) $_{307}$ tials of CO and N₂ are close to each other. One would

³⁰⁸ expect similar behaviors from CO and N₂ molecules in 309 laser fields with the same wavelength and intensity, but we previously proved this is not true [27]. In intense 310 low-frequency laser fields, the multiphoton ionization oc-311 312 curs mainly in the tunneling regime. In this picture, the 313 ionization takes place in the DC field with slow vary-³¹⁴ ing amplitude from zero to its peak value. The width ³¹⁵ of the potential barrier depends on the field strength; ³¹⁶ the stronger the field, the narrower the barrier. Thus 317 the ionization occurs mainly at the peak values of the ³¹⁸ field strength. The probability of tunneling ionization is 319 very sensitive with respect to the HOMO energy. How-³²⁰ ever, in the external field this energy is changed due to the Stark shift. The nitrogen molecule is symmet-321 ³²² ric with respect to inversion, that is why the Stark shift $_{323}$ in a DC field is quadratic in the field strength and the ³²⁴ N₂ molecules HOMO energy differs slightly (0.0001 a.u.) ³²⁵ from its unperturbed value [27]. On the contrary, the car-326 bon monoxide molecule has a permanent dipole moment, ³²⁷ and the DC Stark shift is linear in the field strength; at ³²⁸ the peak values of the field, the HOMO energy can dif-³²⁹ fer significantly (~ 0.1 a.u.) from its unperturbed value $_{330}$ [27]. In our previous studies of CO and N₂ in a linear 331 polarized laser field with the same wavelength and in-³³² tensity the ionization probability of CO is much larger $_{333}$ than that of N₂ [26, 27]. In Figs. 2(b) (CO molecule) $_{334}$ and 2(c) (N₂ molecule) we observe the same phenomena 335 in bichromatic counter-rotating circularly polarized laser ³³⁶ pulses, the ionization probability of CO is much larger $_{337}$ than that of N₂. We also note that ionization of CO $_{338}$ is dominated by HOMO while in N₂ both HOMO and ³³⁹ HOMO-1 have comparable ionization probabilities. This ³⁴⁰ is well explained by the ionization potentials of HOMO-1 341 in these molecules. The ionization potential of HOMO-1 $_{342}$ in N₂ is only 1.4 eV larger than that of HOMO; in CO, ³⁴³ the energy difference between HOMO and HOMO-1 is 345 twice as large, 3.2 eV.

CIRCULARLY POLARIZED HIGH-ORDER IV. 346 HARMONICS IN H_2^+ , N_2 AND CO MOLECULES 347

The observed HHG spectra in Figs. 3-5 can be de-348 scribed in terms of the energy and angular momentum 364 the same doublet. The right peak in the doublet has a 349 conservation in the process of absorption of the driv-350 ³⁵¹ ing fields photons and emission of the harmonic pho-352 ton. [1, 6, 7, 13, 16, 41]. The energy conservation 367 has a circular polarization with the same helicity as the 353 gives $\omega_c = n_1 \omega_1 + n_2 \omega_2$ for the frequency ω_c of the 368 driving field with the lower frequency (E_2) . If we deemitted photon after absorption of n_1 photons of fre- 369 fine $\omega_1 = q\omega_2$, where q can be any number, we obtain ³⁵⁵ quency ω_1 and n_2 photons of frequency ω_2 . The an-³⁷⁰ $\omega_c = n_1(q+1)\omega_2 \pm \omega_2$. For the driving laser wavelengths ³⁵⁶ gular momentum conservation requires $n_2 = n_1 \pm 1$ for ³⁷¹ studied here (790 and 1300 nm), $\omega_c = (2.65n_1 \pm 1)\omega_2$. $_{357}$ the circularly-polarized counter-rotating driving fields E_1 $_{372}$ While the calculated HHG spectra for H⁺₂ and N₂ in $_{358}$ and E_2 . Then the emitted photon frequency can be rep- $_{373}$ Figs. 3 and 5, respectively, show the peak positions match $\omega_c = (2n+1)(\omega_1 + \omega_2)/2 \pm (\omega_1 - \omega_2)/2$, $\omega_1 = 1$ well those predicted by the selection rules and specified $_{360}$ n being a positive integer number. This gives rise to $_{375}$ above, the CO spectrum in Fig. 4 has extra peaks corre- $_{361}$ a doublet structure of the HHG spectrum, with the fre- $_{376}$ sponding to even harmonics with $n_1 = n_2$. Generation of $_{362}$ quency differences $\omega_1 + \omega_2$ between the adjacent doublets $_{377}$ such harmonics is forbidden in atoms and homonuclear

FIG. 2. (Color online) The time-dependent ionization probability of electrons in different spin orbital's of (a) H_2^+ , (b) CO, and (c) N_2 molecules in the counter-rotating circularly polarized laser pulses. The laser pulses have a time duration of 21 optical cycles (~ 55 fs) for ω_1 (790 nm) and 8 optical cycles (~ 35 fs) for ω_2 (1300 nm). The time delay $\Delta \tau \sim 11$ fs.

 $_{365}$ circular polarization with the same helicity as the driv- $_{366}$ ing field with the higher frequency (E_1) , the left peak

 $_{363}$ and $\omega_1 - \omega_2$ between the photon emission peaks within $_{378}$ diatomic molecules where the energy levels have definite

³⁷⁹ parity due to the inversion symmetry. Only the states with the opposite parities are coupled by the dipole interaction (one-photon emission and absorption), there-381 fore absorption of an even number of photons $n_1 + n_2$ 382 cannot be followed by emission of a single photon. This 383 restriction is lifted for oriented heteronuclear diatomic 384 molecules. For the present scheme with two counter-385 rotating circularly polarized driving fields, generation of 386 even harmonics is only possible if $n_1 = n_2$, otherwise 387 conservation of the angular momentum projection does 388 not allow for the photon emission. The excitation of the 389 molecule with absorption of $n_1 = n_2$ photons, however, 390 does not change the angular momentum projection on 391 the z axis, thus the emitted even harmonic photon can-392 not be circularly polarized in the x - y plane. We will 393 discuss polarization of emitted radiation in detail below 394 in Sec. V. 395

In Fig. 3, we present the HHG spectrum of H_2^+ for the 396 ³⁹⁷ driving laser pulse shown in Fig. 1. The spectrum displays harmonics with photon energies up to $\sim 160 \text{ eV}$. 398 The ionization threshold (I_p) for the initially occupied 399 400 $1\sigma_q$ molecular orbital is marked with the green dashed vertical line at 29.9 eV. Figure 3(b) shows the below-401 402 and near-threshold region. As one can see, almost all the peaks in the spectrum exhibit a clear doublet structure 403 with the spacing between the main peaks equal to $\omega_1 + \omega_2$ 404 ⁴⁰⁵ and subpeak separation of $\omega_1 - \omega_2$. According to the gen-406 eral considerations discussed above, the components of the doublet (subpeaks within each main peak) must have 407 $_{408}$ circular polarizations opposite to each other. Fig. 3(c) 409 shows the above-threshold harmonics up to photon en- $_{410}$ ergies of ~ 110 eV. Here the doublet structure of the ⁴¹¹ harmonics is not so distinct as in the below-threshold re-⁴¹² gion, especially for the photon energies larger than 80 eV. 413 We can suggest the following explanation of this observation. High-order harmonics are predominantly generated 414 at times when the laser field reaches its highest strength, 415 ⁴¹⁶ that is near the center of the laser pulse. In the vicinity $_{417}$ of the time moment t_0 , corresponding to the half dura-⁴¹⁸ tion of the laser pulse ($t_0 \approx 27.5$ fs, see Fig. 1), the x and 419 y components of the laser electric field (10)-(11) can be ⁴²⁰ approximated as

$$E_x(t) = F_0 \sqrt{2} \sin \left[\frac{1}{2} (\omega_1 - \omega_2)(t - t_0) \right]$$

$$\times \sin \left[\frac{1}{2} (\omega_1 + \omega_2)(t - t_0) \right],$$
(28)

421

$$E_{y}(t) = -F_{0}\sqrt{2}\cos\left[\frac{1}{2}(\omega_{1} - \omega_{2})(t - t_{0})\right] \times \sin\left[\frac{1}{2}(\omega_{1} + \omega_{2})(t - t_{0})\right].$$
(29)

⁴²² When the frequency difference $\omega_1 - \omega_2$ is small, the com-⁴²⁷ in the center of the laser pulse. Consequently, one can E_{423} ponent $E_{y}(t)$ is larger than $E_{x}(t)$ and approximately E_{428} expect a dominant contribution from the y component 424 represents a monochromatic field with the frequency 429 of the dipole acceleration to the harmonic signal in the $_{425} (\omega_1 + \omega_2)/2$. For the current choice of the laser field pa- $_{430}$ high-energy part of the HHG spectrum. This is indeed ⁴²⁶ rameters, this is clearly seen in Fig. 1 for the optical cycle ⁴³¹ the case, as one can see in Fig. 3(c). Since the two-color

FIG. 3. (Color online) HHG spectrum $S(\omega)$ in the x, y, and total domain of the H_2^+ molecule in the counter-rotating circularly polarized laser pulses. Circularly polarized XUV and soft X-ray HHG spectrum (a) up to ~ 160 eV, (b) belowand near-threshold, and (c) above-threshold. The laser pulses have a time duration of 21 optical cycles for ω_1 (790 nm) and 8 optical cycles for ω_2 (1300 nm). The green vertical dashed line indicates the corresponding ionization threshold (I_p) marked by $1\sigma_g$ threshold. All spectra show a doublet structure, located at positions predicted by energy and spin angular momentum conservation [filled maroon circles (1300 nm) and open teal circles (790 nm)]. The separation within each doublet is $\omega_1 - \omega_2$, and different doublets are separated by $\omega_1 + \omega_2$.

⁴³² nature of $E_y(t)$ is less pronounced in the vicinity of the $_{433}$ time moment t_0 , the doublet structure of the total HHG ⁴³⁴ spectrum is less distinct for higher harmonic orders. The 435 situation will change for the different choice of the laser filed parameters, such as frequencies and time delay between the fields $E_1(t)$ and $E_2(t)$. For example, one may 437 expect a more distinct doublet structure in high-order 438 harmonics for the larger difference between ω_1 and ω_2 . 439

Next, we show the CO molecule (Fig. 4) where it also 440 has odd order circularly polarized harmonics with pho-441 ton energies up to ~ 160 eV. The laser pulse parameters 442 for the CO molecule are the same as those for the H_2^+ 443 molecule in Fig. 3. The ionization threshold (I_n) for the 444 5σ orbital (HOMO) is marked with the green dashed ver-445 tical line at 13.9 eV. Figure 4(b) shows the below- and 446 near-threshold region where the doublets separated from 448 each other by the frequency $\omega_1 + \omega_2$ and containing two harmonics with opposite circular polarizations split by 449 the photon energy of $\omega_1 - \omega_2$ are clearly seen and labeled. 450 Figure. 4(c) shows the above-threshold harmonics up to 451 photon energies of ~ 65 eV. An important difference be-452 $_{453}$ tween the H₂⁺ (Fig. 3) and CO (Fig. 4) spectra is that the ⁴⁵⁴ latter contain even as well as odd harmonics. Generation 455 of even harmonics is forbidden in systems with inver-⁴⁵⁶ sion symmetry, such as atoms and homonuclear diatomic ⁴⁵⁷ molecules. This selection rule does not apply to the het-⁴⁵⁸ eronuclear molecules with no inversion center (CO). This can be clearly seen in the below- and near-threshold har-459 $_{460}$ monic region in Fig. 4(b), where the extra peaks (even harmonics) lie between the adjacent doublets of odd har-461 monics. Unlike the doublets of the odd harmonics, the 462 even harmonics are linearly polarized as they are gener-463 ated solely by the dipole acceleration along the z axis. 464 For example, one can see an even harmonic peak at the 465 466 photon energy $\omega_c = 20.7$ eV in Fig. 4(b), that lies between the adjacent doublets (labeled by the filled maroon 467 circles and open teal circles) of odd harmonics. 468

Intuitively, one expects that the driving field polarized 469 470 in the x (or y, or z) direction induces the dipole moment in the *same* direction. However, this is true only 471 472 for symmetric systems such as atoms and homonuclear diatomic molecules where the polarization tensor is di-473 agonal (with z being the molecular axis in the case of 474 475 diatomic molecules). This intuitive picture is invalid for 476 heteronuclear diatomic molecules where the charge distribution has no inversion symmetry with respect to the 477 478 center of the molecule. Then the force acting perpendicular to the molecular axis (in the x or y direction) would 479 cause a non-symmetric charge displacement along the z-480 axis as well, inducing a dipole moment in this direction. 481 Unlike the permanent dipole moment of a heteronuclear 482 molecule along the molecular axis, this induced dipole 483 moment would oscillate with the driving field thus gen-484 $_{495}$ erating harmonics polarized in the z direction. This phe- $_{490}$ linearly polarized along the z axis (n_1 must be equal to n_2 ⁴⁸⁶ nomenon can be clearly observed in Fig. 4(b), where the ⁴⁹¹ because of conservation of the angular momentum projec- $_{487}$ HHG spectrum has a non-zero contribution $S_z(\omega)$ due $_{492}$ tion: a dipole accelerated along the z axis can only emit $_{488}$ to the dipole acceleration in the z direction. This con- $_{493}$ photons with zero spin projection on this axis). Other

FIG. 4. (Color online) HHG spectrum $S(\omega)$ in the x, y, z, and total domain of the CO molecule in the counter-rotating circularly polarized laser pulses. Circularly polarized XUV and soft X-ray HHG spectrum (a) up to $\sim 170 \text{ eV}$, (b) belowand near-threshold, and (c) above-threshold. The laser pulses have a time duration of 21 optical cycles for ω_1 (790 nm) and 8 optical cycles for ω_2 (1300 nm). The green vertical dashed line indicates the corresponding HOMO ionization threshold (I_p) marked by 5σ threshold. All spectra show a doublet structure, located at positions predicted by energy and spin angular momentum conservation [filled maroon circles (1300 nm) and open teal circles (790 nm)]. The separation within each doublet is $\omega_1 - \omega_2$, and different doublets are separated by $\omega_1 + \omega_2$.

489 tribution is responsible for generation of even harmonics 494 contributions to the HHG spectrum, $S_x(\omega)$ and $S_y(\omega)$,

FIG. 5. (Color online) HHG spectrum $S(\omega)$ in the x, y, and total domain of the N₂ molecule in the counter-rotating circularly polarized laser pulses. Circularly polarized XUV and soft X-ray HHG spectrum (a) up to ~ 170 eV, (b) belowand near-threshold, and (c) above-threshold. The laser pulses have a time duration of 31 optical cycles for ω_1 (790 nm) and 12 optical cycles for ω_2 (1300 nm). Resonance A in panel (b) corresponds to the $3\sigma_g - 2\pi_u$ and $3\sigma_g - 3\sigma_u$ excited-state resonance peaks. The green vertical dashed line indicates the corresponding HOMO ionization threshold (I_p) marked by $3\sigma_a$ threshold. All spectra show a doublet structure, located at positions predicted by energy and spin angular momentum conservation [filled maroon circles (1300 nm) and open teal circles (790 nm)]. The separation within each doublet is $\omega_1 - \omega_2$, and different doublets are separated by $\omega_1 + \omega_2$.

⁴⁹⁹ only in the fact of generation of even harmonics by heteronuclear molecules. Polarization of even harmonics is also different: it is linear and directed along the molec-501 ular axis while the driving fields and odd harmonics are 502 polarized in the plane perpendicular to the molecular axis. As one can see in Fig. 4, even harmonics are strong 504 505 only for low orders (up to ~ 35 eV), and then the sig-⁵⁰⁶ nal $S_z(\omega)$ becomes much weaker than the signals $S_x(\omega)$ 507 and $S_{y}(\omega)$ of odd harmonics. This is not surprising since the natural scale of the plateau region, suggested by the 508 famous semiclassical three-step model [42] and based on the ponderomotive energy, does not apply to the har-510 ⁵¹¹ monic radiation generated by the dipole oscillations in the z direction where no direct force from the driving 512 laser field is present. Only Coulomb forces from the nu-513 clei and other electrons can cause oscillations of the par-514 ticular orbital electron density in this direction. During these oscillations, the electron cannot gain a large kinetic ⁵¹⁷ energy before recombining with the molecular core and ⁵¹⁸ emitting the harmonic photon, unlike the case of motion 519 in the x and y directions under direct influence from the laser field. Consequently, the HHG spectrum of even har-520 521 monics exhibits a shorter plateau region than that in the 522 spectrum of odd harmonics.

Finally, in Fig 5 we show the N_2 molecule where it also 523 has circularly polarized harmonics with photon energies 524 up to ~ 160 eV. In Fig. 5 the laser pulses have a time du-525 ration of 31 optical cycles (~ 82 fs) for ω_1 (790 nm) and 526 12 optical cycles (~ 52 fs) for ω_2 (1300 nm) and the laser fields both have a peak intensity of $F_0 = 2 \times 10^{14} \text{ W/cm}^2$ 528 [Eqs. (12)-(13)]. A longer pulse duration is used for the 529 N_2 molecule to make the doublets containing harmonics 530 531 with opposite circular polarizations (split by $\omega_1 - \omega_2$) 532 more structured and well shaped. The N_2 molecule also produces circularly polarized harmonics with photon en-533 ergies up to ~ 160 eV. The ionization threshold (I_p) for 534 535 the $3\sigma_g$ orbital (HOMO) is marked with the green dashed vertical line at 15.5 eV. Figure 5(b) shows the below-536 and near-threshold region where the doublets separated 537 from each other by the frequency $\omega_1 + \omega_2$ and containing 538 two harmonics with opposite circular polarizations split 539 540 by the photon energy of $\omega_1 - \omega_2$ are clearly seen and la-541 beled. Also, two excited-state resonance peaks $(3\sigma_q - 2\pi_u)$ 542 and $3\sigma_g - 3\sigma_u$) are labeled "A" at 13 eV in Fig. 5(b). 543 Figure. 5(c) shows the above-threshold harmonics up to $_{\rm 544}$ photon energies of ~ 160 eV.

V. ELLIPTICITY AND PHASE OF THE CIRCULARLY POLARIZED HARMONIC SIGNALS

545

546

547

Generation of circularly polarized high-order harmon-548 ⁵⁴⁹ ics by bichromatic counter-rotating circularly polarized 495 are responsible for generation of harmonic doublets with 550 drivers results in harmonic doublets, where in each dou- $_{496}$ circular polarizations in the x - y plane. A qualitative $_{551}$ blet the harmonics are circularly polarized with opposite ⁴⁹⁷ difference between the HHG processes in homonuclear ⁵⁵² handedness, and can span the XUV and soft X-ray re-498 and oriented heteronuclear molecules is, therefore, not 553 gions. Here, we prove the polarizations of the harmonics

FIG. 6. (Color online) (a) Phase and (b) ellipticity of the harmonic signals $[S_x(\omega) + S_y(\omega)]$ from H⁺₂ as a function of photon energy (below-threshold harmonics). The laser parameters used are the same as those in Fig. 3. The filled maroon circles and filled teal circles mark the harmonic peak positions within each doublet. The phases of the harmonics within the same doublet exhibit opposite signs: $\sim \pm \pi/2$).

⁵⁵⁴ are the same as those of the frequency components of the ⁵⁵⁵ driving two-color driving laser field, hence, the harmon-556 ics have circular polarizations with left and right handedness. 557

Suppose we have a monochromatic field with the com-558 559 ponents along x and y:

$$F_x = a\cos(\omega t),$$

$$F_y = b\cos(\omega t + \beta).$$
(30)

560 Generally, the field amplitudes along x and y are different 561 (with their ratio $r_{yx} = b/a$), and there is a phaseshift β $_{562}$ between the field oscillations in x and y directions. Actu-⁵⁶³ ally, Eq. (30) represents an elliptically polarized field; the orientation of the ellipse in the x - y plane depends on 565 the parameters r_{yx} and β . The angle α which determines $_{\rm 566}$ the orientation of one of the ellipse axes with respect to ⁵⁶⁷ the *x*-axis is calculated as:

$$\alpha = -\frac{1}{2}\arctan\left(\frac{r_{yx}^2\sin(2\beta)}{1 + r_{yx}^2\cos(2\beta)}\right).$$
 (31)

569 suming the first axis to be the major axis of the ellipse, 590 threshold harmonics is near unity and the phases are

FIG. 7. (Color online) (a) Phase and (b) ellipticity of the harmonic signals $[S_x(\omega) + S_y(\omega)]$ from H⁺₂ as a function of photon energy (above-threshold harmonics). The laser parameters used are the same as those in Fig. 3. The filled maroon circles and filled teal circles mark the harmonic peak positions within each doublet.

570 the ellipticity parameter is calculated as follows:

$$\epsilon = \sqrt{\frac{\sin^2 \alpha + r_{yx}^2 \sin^2(\alpha + \beta)}{\cos^2 \alpha + r_{yx}^2 \cos^2(\alpha + \beta)}}$$
(32)

571 If the calculated ellipticity parameter ϵ appears greater ⁵⁷² than unity, then the first axis is actually the minor axis, 573 and the ellipticity parameter is given by $1/\epsilon$. From 574 the Fourier transform of the induced dipole acceleration ⁵⁷⁵ (which represents the harmonic field), one can obtain the 576 parameters r_{yx} and β and calculate the ellipticity for the 577 specific frequency ω . The circular polarization ($\epsilon = 1$) is 578 only possible if $\beta = \pm \pi/2$ and $r_{yx} = 1$.

670 In Figs. 6-11, the filled maroon circles and filled teal 580 circles indicate the positions of harmonic peaks within 581 each doublet. The circular polarization of the harmon-582 ics marked with the teal circles has the same handed-⁵⁸³ ness as that of the driving field $E_1(t)$, and the harmonics 584 marked with the maroon circles are polarized with the same handedness as the driving field $E_2(t)$.

Figures 6 (below-threshold region) and 7 (above-⁵⁸⁷ threshold region) show the phase and ellipticity of the ⁵⁸⁸ harmonics in the HHG spectrum of H_2^+ molecule (Fig 3). 566 The second axis has the orientation angle $\alpha + \pi/2$. As-589 As one can see in Fig. 6, the ellipticity of the below-

FIG. 8. (Color online) (a) Phase and (b) ellipticity of the harmonic signals $[S_x(\omega) + S_y(\omega)]$ from CO as a function of photon energy (below-threshold harmonics). The laser parameters used are the same as those in Fig. 4. The filled maroon circles and filled teal circles mark the harmonic peak positions within each doublet. The phases of the harmonics within the same doublet exhibit opposite signs: $\sim \pm \pi/2$).

591 592 left and right handedness. In the above-threshold re- 617 the harmonics do not exhibit circular polarization start- $_{593}$ gion (Fig. 7), the ellipticity and phases start to deviate $_{618}$ ing from the photon energy of ~ 60 eV. ⁵⁹⁴ from the values characterizing perfect circular polarization near the photon energy of $\sim 109 \text{ eV}$. 595

Next, in Figs. 8 (below-threshold region) and 9 (above- 619 596 threshold region) we show the phase and ellipticity of the 597 harmonics in the HHG spectrum of CO molecule (Fig 4). 620 598 599 600 601 ⁶⁰² above. Again, in the below-threshold region (Fig. 8), the ⁶²⁴ high-order harmonics exhibit circular polarization up to 603 ⁶⁰⁴ lar polarization with opposite handedness.
