Abstract:

Ferroelectric BiFeO$_3$ is promising for photovoltaic applications, especially in regard to the exploitation of ferroelectric photovoltaic effects for charge separation. However, its large band gap limits efficient sunlight absorption. Here, we demonstrate a new strategy to effectively tune the band gap of tetragonal BiFeO$_3$ via superlattice
structuring with the ferroelectric BiCrO$_3$. The (BiCrO$_3$)$_n$/(BiFeO$_3$)$_n$ superlattices are found to exhibit conventional ferroelectric properties, but low fundamental band gaps, smaller than either of the parent materials. First-principles calculations reveal that the unexpected band-gap reduction is induced by charge reconstruction due to lattice strain, octahedral distortion, and polarization discontinuity at the BiCrO$_3$ - BiFeO$_3$ interfaces. Ultimately, these results provide a new strategy, in the form of superlattice structuring, which could open the door to the creation of efficient ferroelectric photovoltaics.

I. INTRODUCTION

In the past several decades, researchers have been striving to open different corridors for the production of renewable energy. In this regard, photovoltaics (PVs) have been demonstrated to be a promising renewable energy technology to harvest solar energy [1-3], one of the most abundant energy sources available on Earth[4]. Generally, the performance of PV materials is quantified by the power conversion efficiency (PCE), which can be related to the photovoltage and photocurrent. Recently, building from initial interest in single-crystal and ceramic materials over four decades ago [5], a rejuvenation of interest in the so-called anomalous photovoltaic effect in non-centrosymmetric thin-film ferroelectrics has driven an urgent search for new materials in this space. Contrary to traditional semiconductor-based PVs, the photovoltage of ferroelectrics is not limited by their band gap, but can be a few orders of magnitude larger than the optical band gap of material itself [5,6]. In some cases, the photovoltage has been found to be $>10^4$ V [2,6]. Generally the photovoltage is proportional to the magnitude of the electric polarization [6-9]; however, the PCE of ferroelectric materials is normally limited by their small photocurrent density, typically on the order of nA/cm$^2$, which mainly originates from the large intrinsic band gap of these materials (typically 3-4 eV) [2,10]. It is, therefore, of significant importance to lower the band gap of ferroelectric materials without affecting the ferroelectric polarization in an attempt to improve the PCE in PV applications. This is also of great importance for fully characterizing ferroelectric photovoltaic effects, including understanding the performance limits of these devices. While ferroelectric
semiconductors do exist [11], for reasons yet to be understood, the largest effects have been observed in oxides, and therefore finding better oxide materials is a key challenge in the field.

A focus has been in BiFeO$_3$ due to its intrinsic, relatively low band gap (2.67-3.1 eV) [12] and high polarization (90-158 μC/cm$^2$) [13-15]. Importantly, the BiFeO$_3$ has been widely investigated for PV applications and so far shows better PCE efficiency than most of other ferroelectric materials [2,16-20], making it a highly desirable ingredient in fabricating new ferroelectric photovoltaics. Despite these successes, however, BiFeO$_3$ can only absorb UV light, which constitutes only ~20 % of the entire solar spectrum; leaving most of the solar energy incident on Earth unexploited [21]. In epitaxial BiFeO$_3$ thin films, there are several possible phases, including structures derived from monoclinic, triclinic, orthorhombic, and tetragonal parent structures. Of particular note is the tetragonal-like phase, which is actually a slightly monoclinically-distorted tetragonal structure, and has a large $c/a$ lattice parameter ratio of ~1.26 and a giant spontaneous polarization approaching ~150 μC/cm$^2$. With this in mind, it is meaningful to reduce the band gap of tetragonal-like BiFeO$_3$, while maintaining the large spontaneous polarization, to enhance the PCE. On the other hand, BiCrO$_3$ is another ferroelectric material, also with an active lone-pair on the bismuth cation [22], which is often used to tune the band gap and photocurrent of BiFeO$_3$ [23-26], e.g. through alloying. We have recently studied alloyed BiCrO$_3$-BiFeO$_3$ films and found that chromium substitution can help to reduce the band gap by ~0.8 eV for solid solution films and improves charge transport [27].
BiCrO$_3$/BiFeO$_3$ bilayer films, synthesized using a sol-gel technique, were found to exhibit a band gap of ~2.25 eV (smaller than the value of 2.64 eV of BiFeO$_3$) and a short circuit photocurrent density of 0.08 mA/cm$^2$ (higher than the value of 0.007 mA/cm$^2$ for a single-layer BiFeO$_3$ film) [28]. Multiferroic BiFeO$_3$/BiCrO$_3$ heterostructures have also been studied experimentally [10], and it was reported that the photocurrent density and photovoltage can be tuned by the thickness and the number of BiFeO$_3$/BiCrO$_3$ bilayers and that the highest photocurrent density value (~0.013 mA/cm$^2$) was recorded in 60-nm-thick heterostructures (including two BiFeO$_3$/BiCrO$_3$ bilayers with each layer of thickness of 15 nm).

More recently, significant band-gap reduction has been realized in double-perovskite Bi$_2$CrFeO$_6$, in which $B$-site-cation ordering controlled by film synthesis results in a remarkable PCE over 8.1 % under AM 1.5G irradiation [21]; a new record for inorganic perovskites in conventional solar-cell applications. The mechanism of enhanced visible-light absorption and its correlation with cation ordering in the double-perovskite Bi$_2$CrFeO$_6$, however, is not clear. It is well known that for perovskites, achieving $B$-site-cation ordering is very difficult (and it is particularly sensitive to oxygen partial pressure and growth temperature) as the thermodynamic window allowing for the realization of such ordered states is extremely narrow. This has been shown true in a number of systems, including La$_2$VMnO$_6$ [29], La$_2$CrFeO$_6$ [30], and La$_2$NiMnO$_6$ [31], etc. On the other hand, superlattice ordering is also a powerful method to engineer ordered double-perovskite structures. For example, long-range ferromagnetism has been
reported in LaCrO$_3$/LaFeO$_3$ superlattices, which is unexpected, given that both LaCrO$_3$ and LaFeO$_3$ are antiferromagnetic \[32\]. Therefore, by creating an atomically-ordered state via superlattice structuring of the aforementioned BiFeO$_3$ and BiCrO$_3$, one might expect to yield interesting electronic structure and material properties, distinct from alloys. There has been limited studies on BiCrO$_3$/BiFeO$_3$ superlattices, and those which do exist have focused mainly on traditional ferroelectric behavior. For example, using a scanning non-linear dielectric microscope, researchers found that the polarization in such superlattices is reversible and thus suggested that the superlattices are ferroelectric at room temperature \[33\]. The ground state properties of BiFeO$_3$/BiCrO$_3$ superlattices, such as the electronic structure, intrinsic band gap, and ferroelectric polarization, are, however, not well developed.

Here, we report a density functional theory (DFT) investigation of the lattice geometrical and electronic properties of (BiCrO$_3$)$_m$(BiFeO$_3$)$_n$ superlattices. Systematic study shows that the band gap of the superlattices is widely tunable, and can take values well below those of either component by itself, while still maintaining the ferroelectric polarization. Unexpectedly, the optimized band gap of $\sim$1.6 eV for the BiCrO$_3$/BiFeO$_3$ superlattice is not only smaller than both the single-layer BiFeO$_3$ and BiCrO$_3$, but is also smaller than the equivalent Bi(Fe,Cr)O$_3$ alloy \[27\]. This surprising result is the consequence of charge reconstruction due to lattice strain, octahedral distortion, and polarization discontinuity at the superlattice interfaces. We also show that the ferroelectric and magnetic properties of the superlattice are not strongly affected. These results demonstrate that superlattice structuring can be an
effective strategy for the design of low band gap oxide semiconductors with fundamental band gaps much smaller than either parent materials, thus opening new perspectives for ferroelectric PVs.

II. COMPUTATIONAL DETAILS

All of the spin-polarized calculations are carried out based on the DFT, using the Vienna ab-initio Simulation Package (VASP) code [34,35]. For the exchange and correlation energy, the Perdew-Burke-Ernzerhof functional [36] under the generalized gradient approximation (GGA) is employed. The on-site Coulomb interaction presented in 3d states of transition-metal ions are corrected by the DFT+U (where U is the Hubbard energy) method [37]. The dependence of the lattice parameters and band gap for BiFeO₃ on the effective U value are presented [Fig. 1(a) and (c)]. It is shown that as the U_{eff} value increases, the lattice parameter a and c/a deviate from and approach to the experimental values, respectively. On the other hand, the band gap increases till U_{eff}=3 eV and further increase has slight influence on the band gap. For BiCrO₃, similar trend is observed. Consequently, the U_{eff}=4 eV [27,38] is employed for both Fe 3d and Cr 3d states in this work. A cutoff energy of 500 eV for plane-wave basis set and a 4×4×4 Monkhorst-Pack k-mesh for Brillouin-zone integrations are used for structural relaxation. The convergence criteria for total energies and forces are 10^{-4} eV and 10^{-4} eV/Å, respectively. During the structural optimization, a full relaxation is employed. The spontaneous polarization is evaluated by simply summing the product of atomic displacements and corresponding Born effective charges (BECs)
[39], which are calculated using density functional perturbation theory with a $2\times2\times2$ Monkhorst-Pack k-mesh. For bulk BiFeO$_3$ (BFO) and BiCrO$_3$ (BCO), all computations are based on a $2\times2\times2$ supercell containing 40 atoms. For the $(\text{BiCrO}_3)_m/(\text{BiFeO}_3)_n$ ((BCO)$_m$/BFO)$_n$ superlattices, which consist of m unit cells of BiCrO$_3$ alternating with n unit cells of BiFeO$_3$, different alternating periodic cells, i.e., (BCO)$_n$/BFO)$_1$ and (BCO)$_1$/(BFO)$_n$ (m, n = 1, 2, 3, 4, 5), are considered.

III. RESULTS AND DISCUSSION

A. Ground state properties of bulk BFO and BCO

The tetragonal-like phase of BFO with a space group of $P4mm$ has a large $c/a$ lattice parameter ratio (1.255-1.27) [12,40], where $O_A$ and $O_B$, respectively, belong to the FeO and BiO layers [Fig. 2 (a)]. Clearly, one Fe$^{3+}$ is coordinated by six O$^{2-}$ ions and an octahedron is formed. In the literature, it has been reported that the tetragonal-like BFO has G- and C-type antiferromagnetic spin states [38,41]. Schematic views of the spin configurations of BFO are illustrated [Fig. 2(b)-(c)]; in this work, both G- and C-type ordering are considered for bulk BFO and BCO.

For bulk BFO, the obtained lattice parameters of $a = 3.755$ Å and $c/a = 1.300$ for G-type ordering are close to the calculated values of 3.753 Å and 1.303, respectively, for C-type ordering; both are in good agreement with the experimental values of 3.72 Å and 1.255 [40], respectively. The calculated magnetic moment of Fe is 4.136 $\mu_B$/atom for G-type ordering, agreeing well with the prior theoretical value of 4.18 $\mu_B$/atom [42] and the experimental value of 4.34 $\mu_B$/atom [43], and it is comparable to
the result of 4.130 $\mu_B$/atom for C-type ordering. Both G- and C-type ordered BFO exhibit direct band gaps and the values of band gap are 1.62 and 1.71 eV, respectively; which are smaller than the experimental data of 3.1 eV [12,44,45]. This is a generic problem in DFT, which persists in the PBE+U calculations, with U=4 eV. Higher values of U have slight effects on the band gap, and so we use $U=4$ eV, and correct the band gap using a scissors operation [46,47] based on the known experimental gap of BiFeO$_3$ and BiCrO$_3$ (see the part C of section III). Our calculations show that the geometrical structure, band structure and Fe magnetic moment of G- and C-type ordered tetragonal BFO are similar to each other, which is consistent with previous theoretical studies [38]. We also find that the total energy difference between G- and C-type ordered BFO is only 0.068 eV, indicating that the stability of these two orderings are comparable.

For bulk G- and C-type ordered BCO, the obtained magnetic moment of Cr and the lattice parameters are, like for the case of BFO, similar to each other [Table 1]. For G-type ordered BCO, the calculated lattice parameters are $a = 3.926$ Å and $c = 4.073$ Å, which are comparable to the experimental results of $a = 3.888$ Å and $c = 3.902$ Å [48]. On the other hand, the band gap of 0.94 eV for G-type ordering is higher than the value of 0.69 eV for C-type ordering, and both values are smaller than the experimental value of 2.37 eV [28]. The calculated band gap of BCO (0.94 eV for G-type and 0.69 eV for C-type) are smaller than those of BFO (1.62 eV for G-type and 1.71 eV for C-type), consistent with the experimental results. [12,28]. In addition, the total energy of the G-type ordering is 0.156 eV smaller than C-type
ordering, *i.e.*, the G-type ordering BCO is energetically more preferable. Hence, in the subsequent calculations, we only consider the BFO and BCO with G-type ordering.

**B. Geometrical structures of the superlattices**

Fig. 2(d) illustrates the geometrical structure for the optimized (BCO)$_1$(BFO)$_1$ superlattice. The optimized structural parameters of (BCO)$_m$(BFO)$_1$ and (BCO)$_1$(BFO)$_n$ superlattices are also presented [Table 2], including data for bulk BFO and BCO. The calculated lattice constant $a$ and average $c/a$ ratio as a function of $m$ and $n$ are also plotted [Fig. 3 (a)]. It is found that the in-plane lattice constant $a$ of (BCO)$_m$(BFO)$_1$ increases with increasing BCO layers, and the in-plane lattice constant of (BCO)$_1$(BFO)$_n$ decreases with increasing BFO layers, owing to the strain effect caused by the lattice mismatch between BFO and BCO. To the contrary, as can be seen [Fig. 3(b)], the average out-of-plane lattice constant $c$ of the superlattices decreases with increasing BCO layers and increases with increasing BFO layers. For displacive ferroelectric materials, the $c/a$ ratio reflects the tetragonal distortion, which is a consequence of the spontaneous polarization. Therefore, the observed increase of $c/a$ ratio indicates an increase of relative displacement between cations and anions, resulting in enhanced polarization [49,50]. The $c/a$ ratio decreases with increasing BCO layers and increases with increasing BFO layers [Fig. 3(b)], indicating that the polarization of the (BCO)$_1$(BFO)$_n$ superlattices is larger than that of the (BCO)$_m$(BFO)$_1$ superlattices. This is seen directly in the polarization discussed in the next section. It is thus expected that the electrical and optical properties of the
(BCO)\textsubscript{m}/(BFO)\textsubscript{n} superlattices can be adjusted by tuning the stacking period, which will alter the ground-state structure of superlattices due to strain effects [50].

The average interlayer distance $\Delta d$ (the thickness of one monolayer, which is equivalent to the local out-of-plane lattice constant) and the bond angles $\angle O_A$-Cr-$O_B$ and $\angle O_A$-Fe-$O_B$ in BFO, BCO and the (BCO)\textsubscript{m}/(BFO)\textsubscript{n} superlattices are also summarized [Table 2]. We find that all the values of $\Delta d_{BFO}$ for superlattices are smaller than the value of 4.879 Å for bulk BFO and the values of $\Delta d_{BCO}$ are larger than the value of 4.073 Å for bulk BCO, indicating that the BFO in the (BCO)\textsubscript{1}/(BFO)\textsubscript{n} superlattices is compressed, while the BCO in the (BCO)\textsubscript{m}/(BFO)\textsubscript{1} superlattices is stretched along the [001] direction in comparison to their bulk values. This is resulted from the interface stress caused by the large lattice mismatch (4.3 \%) between the BFO and BCO, since the lattice constant of BFO (3.755 Å) is much smaller than that of BCO (3.926 Å). For the (BCO)\textsubscript{m}/(BFO)\textsubscript{1} superlattices, as the number of BCO layers increases from 1 to 5, $\Delta d_{BFO}$ decreases from 4.456 to 4.166 Å, and $\Delta d_{BCO}$ decreases from 4.327 to 4.094 Å. Obviously, for the thicker BCO layers, the interlayer spacing of BFO is far from that in the bulk state and the interlayer distance between BCO layers becomes close to that in the bulk. Correspondingly, the $\angle O_A$-Fe-$O_B$ angle deviates much more from the 110.7° in the bulk state and the $\angle O_A$-Cr-$O_B$ angle approaches the 96.6° in the bulk state. These results suggest that the thicker BCO layers lead to significant compression of the BFO and large relaxation of BCO layers along the [001] direction. As for the (BCO)\textsubscript{1}/(BFO)\textsubscript{n} superlattices, when the BFO layer is increased in thickness from 1 to 5 unit cells, the BFO layer is
compressed and the BCO layer is expanded considerably, resulting in $\Delta d_{BFO}$ and $\angle O_A{-}Fe{-}O_B$ approaching the bulk values for BFO and $\Delta d_{BCO}$ and $\angle O_A{-}Cr{-}O_B$ deviating significantly from the bulk values for BCO. Comparing the bond angles $\angle O_A{-}Cr{-}O_B$ and $\angle O_A{-}Fe{-}O_B$ in both the (BCO)$_1$/(BFO)$_n$ and (BCO)$_m$/(BFO)$_1$ superlattices, we find that both angles in the (BCO)$_1$/(BFO)$_n$ superlattices are larger than those in the (BCO)$_m$/(BFO)$_1$ superlattices, indicating that the distortion of the octahedra in the tetragonal lattice of the (BCO)$_1$/(BFO)$_n$ superlattices is more significant, which results in larger $c/a$ ratio and polarization [49]. This is in good agreement with the discussions in above section. It is obvious that the induced structural deformation and octahedral distortion in the (BCO)$_1$/(BFO)$_n$ and (BCO)$_m$/(BFO)$_1$ superlattices are different, indicating that they may exhibit different electronic structures and polarization.

The formation of these superlattices can be quantitatively estimated by their respective formation energy, which reflects the total energy cost during the superlattice structuring of the two parent compounds BFO and BCO. The formation energies of (BCO)$_m$/(BFO)$_n$ superlattices as compared to bulk BFO and BCO are calculated and the results are summarized [Table 3]. The formation energy is defined as $E=E_{(BCO)_m/(BFO)_n}-nE_{bulkBFO}-mE_{bulkBCO}$. Here, $E_{(BCO)_m/(BFO)_n}$, $E_{bulkBFO}$ and $E_{bulkBCO}$ are the total energies of (BCO)$_m$/(BFO)$_n$ superlattices, bulk BFO and bulk BCO, respectively. As shown in Table 3, the (BCO)$_1$/(BFO)$_1$ superlattice has the lowest formation energy of 1.94 eV among the considered superlattices, and the formation energies of (BCO)$_m$/(BFO)$_1$ and (BCO)$_1$/(BFO)$_n$ superlattices increase with the
increasing layer number of BCO and BFO, respectively. It is also noted that the formation energy of (BCO)\textsubscript{m}/(BFO)\textsubscript{1} is relatively smaller than that of (BCO)\textsubscript{1}/(BFO)\textsubscript{n} (m=n=2, 3, 4, 5). These results suggest that as the layer number of BFO or BCO is increased the (BCO)\textsubscript{m}/(BFO)\textsubscript{1} and (BCO)\textsubscript{1}/(BFO)\textsubscript{n} superlattices become more difficult to form, and the (BCO)\textsubscript{1}/(BFO)\textsubscript{n} superlattices are relatively more difficult to form than the (BCO)\textsubscript{m}/(BFO)\textsubscript{1} superlattices.

In order to investigate if the superlattice structures are mechanically stable, we select the (BCO)\textsubscript{1}/(BFO)\textsubscript{1} superlattice as a model system and calculate its elastic constants. The obtained elastic constants are C\textsubscript{11} of 260.1 GPa, C\textsubscript{33} of 64.4 GPa, C\textsubscript{44} of 79.1 GPa, C\textsubscript{66} of 59.4 GPa, C\textsubscript{12} of 75.3 GPa and C\textsubscript{13} of 78.3 GPa, which satisfy well the Born stability criteria, i.e., C\textsubscript{11} > 0, C\textsubscript{33} > 0, C\textsubscript{44} > 0, C\textsubscript{66} > 0, (C\textsubscript{11} - C\textsubscript{12}) > 0, (C\textsubscript{11}+C\textsubscript{33}-2C\textsubscript{13}) > 0, [2(C\textsubscript{11}+C\textsubscript{12})+C\textsubscript{33}+4C\textsubscript{13}] > 0, indicating that the (BCO)\textsubscript{1}/(BFO)\textsubscript{1} superlattice is mechanically stable. The lattice mismatch between bulk BFO and BCO is about 4.3 %. Experimentally, the LaAlO\textsubscript{3}/BaTiO\textsubscript{3}, PbTiO\textsubscript{3}/PbZrO\textsubscript{3}, and BaZrO\textsubscript{3}/SrTiO\textsubscript{3} superlattices, for which the lattice mismatch are 5.3 %, 5.3 % and 6.9 %, respectively, have been synthesized successfully by Zuo et. al. [51], Choi et. al. [52] and Christen et. al. [53], respectively. Hence, the BFO/BCO superlattice, with a lattice mismatch of ~ 4.3 %, is possible to be synthesized with an appropriate substrate. Recently, the supertetragonal phase of BFO has been successfully synthesized by various groups via epitaxial stabilization on LaAlO\textsubscript{3} and YAlO\textsubscript{3} with pulsed laser deposition method [54-57]. Considering suitable lattice match for both BFO and BCO, we propose LaAlO\textsubscript{3} can be a very good candidate for the
C. Electronic structures of the superlattices

Based on the optimized structures, we further calculate the band structures of the (BCO)$_m$(BFO)$_n$ and (BCO)$_1$(BFO)$_n$ superlattices. In this study, an approach of reverse scissor correction procedure is employed. This is an empirical correction consisting of a shift of the conduction regions up and can be applied to both GGA and LDA underestimated band gaps, especially in the determination of band-gap offsets for interfaces between different semiconductors [46,58,59]. The scissor correction method has been extensively employed in a number of calculations and the predicted band gap and optical properties were found to agree well with experiments [47,60-62].  Here we use a scissor operator of 1.48 eV, which corrects not only the band gap of BFO to 3.1 eV but also the band gap of BCO to 2.42 eV, agreeing well with the experimental values of 3.1 eV [12,45] and 2.37 eV [28], respectively. The scissor operator of 1.48 eV is also applied to the (BCO)$_m$(BFO)$_n$ superlattice structure.

The variation of the reverse scissor corrected band gap for (BCO)$_1$(BFO)$_n$ and (BCO)$_m$(BFO)$_1$ superlattices as a function of the number of BFO and BCO layers [Fig. 4(a)] and the calculated band structures [Fig. 5] are presented. It is shown that all the superlattices retain the direct band gap character, similar with that of BFO. Besides, based on the calculated results, it appears that the charge hybridization and carrier transport will mainly occur within the tetragonal plane rather than along the $c$
axis, since the dispersion occurs along the G-X, X-M and M-G directions while the bands are flat along the G-Z direction [63]. The band gap of the superlattices is observed to decrease markedly with the number of layers of BFO and/or BCO in a given stack height [Fig. 4(a)]. The band gap of the (BCO)_n/(BFO)_m superlattices are lower than that of the (BCO)_m/(BFO)_1 superlattices for the same values of n and m (n, m>1). The band-gap values for the superlattices are located within the range of 1.59-1.96 eV, which are unexpectedly smaller than the parent materials.

In order to verify if the scissor correction results for the superlattice structure are reliable, a series of DFT/meta-GGA calculations with mBJ (modified-Becke-Johnson) functional are also carried out. The DFT/meta-GGA method with mBJ functional (DFT/meta-GGA-mBJ) has been reported to yield band gaps with an accuracy similar to hybrid functional or GW methods for various semiconductors/insulators but computationally less expensive [64]. We have performed DFT/meta-GGA-mBJ calculations on BFO, BCO and (BCO)_m/(BFO)_1 (m=1 to 5) superlattices and a comparison of the obtained band gap by DFT, DFT with scissor correction and DFT/meta-GGA-mBJ calculations is listed in Table 4. For bulk BFO and BCO under DFT/meta-GGA-mBJ scheme, the weight parameters (cmBJ values) of 1.4 and 1.3 are employed, respectively, and the obtained band gap of 2.92 eV for bulk BFO and 2.27 eV for bulk BCO are in good agreement with the experimental values of 3.1 [12,45] and 2.37 eV [28], respectively. These cmBJ values are then applied to the (BCO)_m/(BFO)_1 (m=1 to 5) superlattices. It is noticeable that the band gap values predicted by scissor corrections compare well with those obtained from
DFT/meta-GGA-mBJ and both methods predict similar band gap variation trend, confirming the reliability of the current predicted band gap values.

Furthermore, the obtained value (1.59 -1.96 eV) is also substantially smaller than that of the alloyed Bi(Fe,Cr)O3 sample [27]. Similar results wherein the band gap of a composite compound is smaller than that of the parent materials have also been reported in superlattices of (GaN)_n/(ZnO)_1 [65] and (0001)-oriented wurtzite (GaN)_n/(AlN)_n (n = 10, 12, 14) [66] as well as nanocomposites of Carbon-ZrO2 [67], NiO:TiO2 [68] and Fe2O3-Cr2O3 systems [69-71].

For the band gap reduction with the increasing layer number of BFO or BCO, the lattice strain induced by the lattice mismatch between BFO and BCO may be one of the reasons responsible for that. In order to explore how the lattice strain influences the band gap, we investigate the band gap of BFO and BCO within 2 % tensile and compressive strain, respectively. The variation of band gap as a function of strain is illustrated [Fig. 4(b)]. It is shown that the band gap of both BFO and BCO decreases monotonously with decreasing the compressive strain and increasing the tensile strain level. This predicted trend is consistent with recent experimental observation that film epitaxially grown on compressive substrate (e.g. LaAlO3 and YAIO3) exhibits relatively larger optical band gap than on tensile substrate (e.g. DyScO3) [44,45,72,73].

For (BCO)_m/(BFO)_1 superlattices, the interlayer distances between BCO layers are comparable to that of bulk BCO and the interlayer distances between BFO layer are much smaller than that of bulk BFO, i.e., the tensile strain of BFO dominates in
the (BCO)\textit{m}/(BFO)\textit{l} superlattices and the tensile strain increases with the increasing layer number of BCO. As for (BCO)\textit{l}/(BFO)\textit{n} superlattices, the interlayer distances between BFO layers are comparable to that of bulk BFO and the interlayer distances between BCO layer are much larger than that of bulk BCO, i.e., the compressive strain of BCO dominates in the (BCO)\textit{l}/(BFO)\textit{n} superlattices and the compressive strain increases with the increasing layer number of BFO.

It should be pointed out that the (BCO)\textit{m}/(BFO)\textit{n} superlattice cannot be free-standing experimentally and a suitable substrate is necessary. Considering the error between calculated values and experimental measurements, the in-plane lattice constants of (BCO)/(BFO) superlattices would vary from 3.738 to 3.885 Å. Therefore, the LaAlO\textsubscript{3} (LAO), with a lattice constant of 3.79 Å, will be a suitable substrate for the synthesis of BFO/BCO superlattice. The lattice mismatch between the substrate and the superlattice structure is estimated to be 1.3~2.5 % and the induced lattice strain varies from -2.4 % to 1.4 %. We also study the strain effect on the band gap of the superlattice. The representative results of (BCO)\textit{l}/(BFO)\textit{l} and (BCO)\textit{l}/(BFO)\textit{8} are also shown in Fig. 4(b). It is clearly seen that the superlattice demonstrates similar trend of strain dependent band gap as single phase of BFO and BCO. However, the band gap variation is much smaller, for example, the band gap of (BCO)\textit{l}/(BFO)\textit{l} superlattice change from 2.06 to 1.94 eV corresponding to -2% compressive strain to 2% tensile. Therefore, the epitaxial strain is not expected to significantly impact the band gap values of the superlattice systems.

In order to understand the origin of the unexpected band-gap reduction, further
electronic structure calculations are necessary. The partial charge density distributions at the valence-band maxima (VBM) and conduction-band minima (CBM) for BFO, BCO and the (BCO)$_1$(BFO)$_5$ and (BCO)$_5$(BFO)$_1$ superlattices are illustrated [Fig. 6]. It is found that holes at the VBM for BFO are mainly contributed by two types of oxygen anions, while the electrons at the CBM are mainly located on the A-site Bi and O$_A$ atoms, respectively, and also slightly on the B-site Fe atom. For the BCO, the charge density distribution is remarkably different, the holes at the VBM are mainly gathered on the two types of O atoms as well as on B-site Cr atoms, while the electrons at the CBM are mainly contributed by the A-site Bi and O$_A$ atoms, respectively. The different valence/conduction band characteristics of these two compounds originate from the different electron negativity of the transition-metal cations and thus the different electronic structures of BFO and BCO. The valence bands of BFO are mainly contributed by O 2$p$ orbitals, whereas the O 2$p$ and Cr 3$d$ states dominate the valance bands of BCO in the band edge near the Fermi level [Fig. 7] due to the slight higher atomic energy position for Cr 3$d$ orbitals than Fe 3$d$ orbitals.

These results indicate that electron redistribution should be expected when the BFO and BCO are incorporated simultaneously in the same superlattice structures. Comparing the charge distribution of the (BCO)$_1$(BFO)$_5$ superlattice with that of bulk BFO and BCO, we find that the holes at the VBM for the (BCO)$_1$(BFO)$_5$ superlattices are mainly contributed by the interfacial Cr 3$d$ and O 2$p$ orbitals, and the electrons at the CBM are mainly gathered on the interfacial Fe 3$d$, Bi 6$p$, and a few O$_A$ 2$p$ orbitals. For the (BCO)$_5$(BFO)$_1$ superlattices, the charge distribution of the
VBM and the CBM are similar to the (BCO)\(_n\)/(BFO)\(_s\) superlattices, where the holes at the VBM are mainly contributed by the Cr and O\(_b\) ions and the electrons at the CBM are mainly gathered on the Bi and O\(_a\) ions. The atomic projected density of state distribution for bulk BFO, bulk BCO, (BCO)\(_1\)/(BFO)\(_n\) and (BCO)\(_m\)/(BFO)\(_s\) (n, m=1, 3, 5) superlattices is illustrated [Fig. 7]. It is noted that the Fermi level of the BFO is shifted to higher binding energy when the superlattice structure is formed, accompanied by the upward shift of the valence bands. As compared with the DOS distribution of (BCO)\(_1\)/(BFO)\(_1\) superlattice, it is noted that the Fermi levels shift slightly to the higher binding energy level and lower binding energy level for (BCO)\(_1\)/(BFO)\(_n\) and (BCO)\(_m\)/(BFO)\(_s\) superlattices, respectively. As for (BCO)\(_1\)/(BFO)\(_n\) superlattices, the valence bands are mainly contributed by O 2p and Fe 3d states; in the case of (BCO)\(_m\)/(BFO)\(_1\) superlattices, the O 2p and Cr 3d states dominate the valence bands. Also, the conduction bands of (BCO)\(_1\)/(BFO)\(_n\) and (BCO)\(_m\)/(BFO)\(_s\) superlattices exhibit different character. For the (BCO)\(_1\)/(BFO)\(_n\) superlattices, the conduction bands shift towards Fermi level. Consequently, the band gap of the (BCO)\(_1\)/(BFO)\(_n\) and (BCO)\(_m\)/(BFO)\(_s\) superlattices is much lower than that of BFO.

D. Spontaneous polarization

An excellent ferroelectric PV material should have not only a low band gap and high photocurrent, but also a large spontaneous polarization. The polarization can be estimated by \(\Delta P = \sum_{\alpha} \frac{\partial p_\alpha}{\partial \mu_\beta} \left(\mu_\beta - \mu_{0j\beta}\right) = \frac{\varepsilon}{n} \sum_{j\beta} Z^\ast_{j\alpha\beta} \Delta \mu_{j\beta}\), where \(\Delta \mu_{j\beta}\) is the...
displacement of ions \( j \) in Cartesian direction \( \beta \), \( Z_{j\alpha\beta}^* \) is the Born effective charge tensor, \( e \) is the charge of an electron and the \( \Omega \) is the cell volume [39]. In this work, cubic BFO is used as the centrosymmetric reference structure, which is described by the zero subscript. The calculated polarization for the tetragonal-like BFO by this method is 142.3 \( \mu \text{C/cm}^2 \); agreeing well with the experimental data of 150–158\( \mu \text{C/cm}^2 \) [13,40] and other prior calculated values of 136–145 \( \mu \text{C/cm}^2 \) [57,74,75]. The polarization as a function of BFO and BCO layer number is plotted [Fig. 8]. It is shown that the polarization of all superlattices are located in the range of 64.8-131.0 \( \mu \text{C/cm}^2 \). The polarization of the superlattices decreases with the increasing number of BCO layers, but increases with the increasing BFO layers, which is similar to the variation of the \( c/a \) ratio with layer number of both BFO and BCO. A similar dependence has been reported in tetragonal \((\text{BaZrO}_3)_m/(\text{BaTiO}_3)_n\) superlattices that have a large \( c/a \) ratio and large polarization [50]. We find that the polarization of the superlattices are mainly contributed by the transition elements and the \( \text{O}^{2-} \) ions, and the contribution of \( \text{O}_A \) is larger than that of \( \text{O}_B \). Besides, the direction of polarization of transition elements is in opposition to that of O and Bi atoms. In addition, the polarization of 92.9-131.0 \( \mu \text{C/cm}^2 \) for the \((\text{BCO})_i/(\text{BFO})_h\) superlattices is larger than the polarization of 64.8-92.9 \( \mu \text{C/cm}^2 \) for the \((\text{BCO})_m/(\text{BFO})_1\) superlattices, and the value of 131.0 \( \mu \text{C/cm}^2 \) for the \((\text{BCO})_i/(\text{BFO})_5\) superlattices is the largest among all the investigated superlattices. This likely arises from the combined effects of lattice strain in the BFO layers due to lattice mismatch and the distorted octahedra in both the BFO and BCO.
In this study, a DFT+U method is employed to investigate the band gap and polarization of (BCO)\textsubscript{m}/(BFO)\textsubscript{n} superlattices. In order to investigate the effects of the $U\text{eff}$ value on the polarization, the impact of the $U\text{eff}$ value on the Fe partial charge change $\Delta q$ has been investigated for bulk BFO with both G- and C-type AFM states, and the results are plotted [Fig. 9(a)]. It is shown that the $\Delta q$ increases with the increasing $U\text{eff}$ value, i.e., the charge tends to be away from the Fe and localize on its neighboring O ions for both G- and C-type BFO. For G-type BCO, similar trend has been observed. These results suggest that the choice of $U\text{eff}$ value affects the exact value of the atomic charge. The variation of polarization for bulk BFO, BCO and (BCO)\textsubscript{1}/(BFO)\textsubscript{1} superlattices as a function of $U\text{eff}$ value are presented [Fig. 9(b)]. It turns out that the choice of $U\text{eff}$ value has slight influences on the polarization. This is because the polarization is mainly determined by the charge and displacement of all the ions. Although the $U\text{eff}$ value affects the charge of Fe and Cr a lot, it also affects the charge of anions a lot simultaneously, i.e., it is a synergetic effect. On the other hand, the $U\text{eff}$ value has small impact on the displacement of all ions. Consequently, the polarization of the materials is affected slightly by the $U\text{eff}$ values.

The local polarization can also be described by the local displacement between transition-metal cations and oxygen anions in the superlattices [76]. The local displacement between the Cr/Fe and O ions for the (BCO)\textsubscript{1}/(BFO)\textsubscript{5} and (BCO)\textsubscript{5}/(BFO)\textsubscript{1} superlattices along the [001] direction is provided [Fig. 10]. It can be seen that both the displacements of the BFO and BCO part for the (BCO)\textsubscript{1}/(BFO)\textsubscript{5} and (BCO)\textsubscript{5}/(BFO)\textsubscript{1} superlattices fluctuate slightly with increasing distance from the
interface, and there is a sharp decrease at the interface, indicative of a sharp change in the polarization at the BiFeO$_3$/BiCrO$_3$ interface. This polarization discontinuity has been observed in BiFeO$_3$/SrTiO$_3$ [77], LaAlO$_3$/PbTiO$_3$ [76], and PbTiO$_3$/SrTiO$_3$ [78] heterostructures, in which there is an internal electric field and two-dimensional-like electronic gas is formed at the interface. In this study, the polarization discontinuity at the interface and the induced charge reconstruction also contribute to the remarkable reduction in the band gap for the (BCO)$_m$/(BFO)$_n$ superlattices.

**IV. CONCLUSION**

In summary, this work provides a systematic DFT+U investigation of (BCO)$_m$/(BFO)$_i$ and (BCO)$_i$/(BFO)$_n$ superlattices (m, n=1, 2, 3, 4, 5) to understand how the superlattice structuring and periodicity influence the geometrical structure and electronic properties. Due to the lattice mismatch between BCO and BFO, significant compression of the BiFeO$_3$ layer and large relaxation of the BCO layers along the [001] direction are found for the (BCO)$_m$/(BFO)$_i$ superlattices, and considerable expansion of the BCO layer and remarkable relaxation of the BFO layers are found for the (BCO)$_i$/(BFO)$_n$ superlattices. Meanwhile, the octahedral distortion in the (BCO)$_i$/(BFO)$_n$ superlattices is found to be more significant than that in the (BCO)$_m$/(BFO)$_i$ superlattices. For all the considered superlattices, the band gap decreases significantly with increasing number of layers of BFO and/or BCO, and the band gap of the (BCO)$_i$/(BFO)$_n$ superlattices is lower than that of the (BCO)$_m$/(BFO)$_i$ superlattices for any given value of n and m (n, m>1). Additionally, all the
superlattices retain the direct character of the BFO. Surprisingly, the \((\text{BCO})_m/(\text{BFO})_n\) superlattices show significant band-gap reduction by as much as 1.5 eV. The optimized band gap of 1.6 eV is not only smaller than both BFO and BCO, but also smaller than the alloyed \(\text{BiFe}_x\text{Cr}_y\text{O}_3\) samples, thus implying good potential for visible-light absorption. The polarization is found to be 92.9-131.0 \(\mu\text{C/cm}^2\) for the \((\text{BCO})_i/(\text{BFO})_n\) superlattices and 64.8-92.9 \(\mu\text{C/cm}^2\) for the \((\text{BCO})_m/(\text{BFO})_i\) superlattices, among which the value of 131 \(\mu\text{C/cm}^2\) for the \((\text{BCO})_1/(\text{BFO})_5\) superlattice is the largest and comparable to the polarization of BFO. These results demonstrate that superlattice ordering can be a new strategy to design low-band-gap semiconductors with fundamental band gaps much smaller than either parent materials, thus opening new perspective for ferroelectric photovaltics.
