(Dated: March 20, 2020)

To date the realization of magnetoresistive RAM (MRAM) and magnetoelectric RAM (MeRAM) devices relies primarily on ultrathin ferromagnetic-based (FeCoB/MgO) magnetic tunnel junctions. On the other hand, the Heusler family of intermetallics is considered very promising for spintronic applications. Nevertheless, the voltage controlled magnetic anisotropy (VCMA) in ultrathin Heusler-based magnetic-tunnel junction stacks remains unexplored. Here, using the ferrimagnetic Heusler Mn_3Ga as a prototype system, we report *ab initio* calculations of the electric field modulation of magnetism in the Ir/ Mn_3Ga /MgO heterostructure. The trilayer structures with one/three monolayers Ir cap and Mn-Mn termination exhibit large perpendicular magnetic anisotropy (PMA) in contrast to these with Mn-Ga termination which yield in-plane magnetization orientation. We predict giant VCMA coefficients whose magnitude and sign depend on both the interface termination and the Ir cap thickness. The underlying atomistic mechanism lies on the electric-field-induced shifts of the spin-orbit coupling energies of the spin-polarized Ir/*d*-orbitals with different orbital angular momentum symmetries. Our work paves the way for exploiting the unique magnetic properties of ferrimagnetic Heusler compounds for the next generation MeRAM devices.

The engineering of perpendicular magnetic tunnel junctions (p-MTJs) has attracted enormous interest in the development of non-volatile, high-performance and low-power magnetoresistive random access memory (MRAM) devices using the spin-transfer-torque (STT) or spin-orbit-torque (SOT) writing schemes.¹⁻⁵ High magnetocrystalline anisotropy (MCA) for the MTJs is required to endow an easier operation scheme and higher stability for the recorded data against thermal fluctuations during reading.⁶ On the other hand, large MCA entails higher power consumption during the writing process where the magnetization switching by spin-polarized currents inevitably leads to Joule heating.⁷ Thus, one of the present challenges in implementing STT- or SOT-MRAM lies on the reduction of the intrinsic current density for magnetization switching while maintaining high thermal stability for long-term data retention.⁸

The voltage-controlled magnetic anisotropy (VCMA) is a highly promising magnetization switching approach which may enable ultra-low power, highly scalable, and non-volatile magnetoelectric random access memory (MeRAM).^{9,10} The VCMA effect has been experimentally demonstrated in MgO-based MTJs, in the form of voltage-induced ferromagnetic resonance excitations,¹¹ coherent precessional magnetization switching,¹² dynamic magnetization switching,^{13,14} and spin wave excitations¹⁵. Several different voltage-induced mechanisms have been proposed to elucidate the VCMA effect, including modification of the electronic structure at the interface,¹⁶⁻²¹ magnetic dipole moment,⁸ and the Rashba effect.²² Two major challenges for future MeRAM devices are to achieve large perpendicular magnetic anisotropy (PMA) (≥ 2 erg/cm²) and high VCMA efficiency, $\geq 1,000$ fJ/Vm, which will allow higher thermal stability, low-power (< 1 fJ/bit switching energy) and fast (< 1 ns) low-error write operations.²³

To date the realization of STT-MRAM and MeRAM devices relies primarily on ferromagnetic-based heterostruc-

tures, such as FeCoB/MgO MTJs^{24,25}. Unfortunately, the PMA of ultrathin FeCo films arises from the interface between the FM layers and the tunnel barrier and/or the heavy metal (Ta, Hf, Ru) underlayer. The PMA in X/FeCo/MgO (X= Ta, Hf and Ru) heterostructures^{7,26-28} is too weak (less than 2.3 erg/cm²) to overcome thermal fluctuations when the device has a critical dimension less than about 20 nm²⁹. In addition, experiments in FeCo/MgO-based MTJ have reported low VCMA efficiency values in the range from 100 to 300 fJ/Vm depending on the capping material, such as Ta, Au and Ir.³⁰⁻³²

Thus, there is an urgent need in searching and identifying magnetic materials in which the PMA and the VCMA efficiency is high. One of the most promising class of materials are the Heusler compounds among which (I4/mmm space group) Mn_3Ga is considered a prototype system with promising applications in the area of spintronics.^{33,34} Its tetragonal $D0_{22}$ phase is a ferrimagnet exhibiting a unique combination of interesting properties, such as low saturation magnetization,³⁵ high perpendicular uniaxial magnetic anisotropy,³⁶ high spin polarization,³⁷⁻³⁹ high Curie temperature,⁴⁰ and low Gilbert damping constant.³⁷ In contrast, the modulation of PMA and electric field control of magnetism in ferrimagnetic Heusler-based heterostructures remains unexplored thus far.

In this work we investigate the effect of the electronic and magnetic properties of the Ir/ Mn_3Ga /MgO trilayer structures with different Mn_3Ga terminations (as shown in Fig.1) based on first-principles calculations. The thin Ir overlayer was considered because it was shown to increase both the PMA and VCMA efficiency in FeCo-based heterostructures.⁴¹⁻⁴⁵

Density functional theory (DFT) calculations within the projector augmented-wave (PAW) method,⁴⁶ were carried out using the Vienna *ab initio* simulation package (VASP)⁴⁷. We use the generalized gradient approximation (GGA) to describe the exchange-correlation energy as parametrized by Perdew *et al.*⁴⁸. In the $D0_{22}$ structure the two (001)

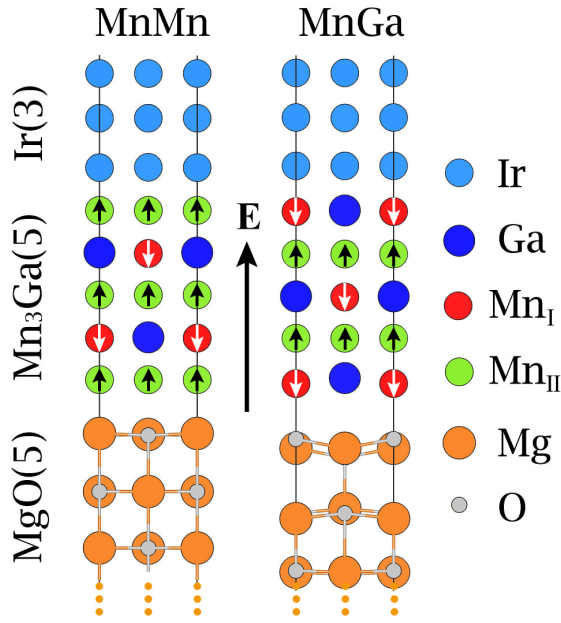

FIG. 1: Schematic atomic structures of the Ir/Mn₃Ga/MgO layers with Mn-Mn (left) and Mn-Ga (right) terminations. The black arrow shows the direction of positive electric field and the z-axis.

antiferromagnetically-coupled Mn sublattices consist of Mn_I atoms located at the Wyckoff positions 2b (0,0,1/2) [Mn_I-Ga plane] and Mn_{II} atoms at the 4d (0,1/2,1/4) positions [Mn_{II}-Mn_{II} plane]. The slab supercell for the Ir(*n*)/Mn₃Ga/MgO heterostructure, shown in Fig.1, consists of *n*=1,3 monolayers (MLs) of fcc Ir placed along [001] atop of 5 MLs Mn₃Ga and 5 MLs of rocksalt MgO underlayer. Here, the interfacial Mn and Ga atoms are placed atop the O atoms of the MgO surface, which are the most stable stacking configurations⁴⁹. The in-plane lattice constant for the Ir(*n*)/Mn₃Ga/MgO heterostructures is set equal to experimental value of 3.92 Å for the tetragonal Mn₃Ga system. This results in a compressive biaxial strain on the MgO of about -6.8 % and a tensile biaxial strain of about +2.1 % on the Ir cap⁵⁰. A 15 Å-vacuum space is adopted to separate the periodic films and the dipole corrections are taken account along [001]. The plane-wave cutoff energy was set to 500 eV and a 16 × 16 × 1 k mesh was used in the Brillouin zone (BZ) sampling for the relaxation calculations. The atomic coordinates are fully optimized until the forces acting on the ions become less than 10⁻² eV/Å, while those for the two bottom-most MgO layers were kept frozen at their relaxed bulk positions. As shown in Fig.1 we considered both the Mn-Mn- and Mn-Ga-terminated interfaces. For the MCA calculations, SOC was included with a 32 × 32 × 1 k-point mesh. The MCA per unit interfacial area is determined from $E_{MCA} = (E_{[100]} - E_{[001]})/A$, where $E_{[100]}$ and $E_{[001]}$ represent the total energy with in-plane and out-of-plane magnetization, respectively, and A is the in-plane area of the unit cell.

Fig. 2 shows the layer-resolved spin moments for the (a) Mn_{II}-Mn_{II}- and (b) Mn_I-Ga-terminated interfaces of the Ir(*n* ML)/Mn₃Ga(5 ML)/MgO(5 ML) heterostructure, for *n*=3 (or-

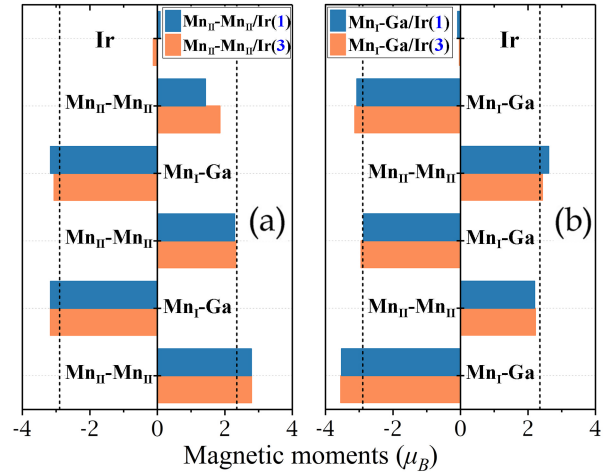

FIG. 2: Layer-resolved magnetic moments for the (a) Mn_{II}-Mn_{II}- and (b) Mn_I-Ga-terminated interfaces of the Ir(*n* ML)/Mn₃Ga(5 ML)/MgO(5 ML) heterostructure, for *n*=3 (orange bars) and *n*=1 (blue bars), respectively. The dashed vertical lines denote the corresponding layer-resolved bulk values.

ange bars) and *n*=1 (blue bars), respectively. Our calculated values of the bulk magnetic moments of -2.90 μ_B and 2.35 μ_B for the Mn_I and Mn_{II} atoms, respectively, denoted by the dashed vertical lines are in good agreement with previous DFT calculations^{34,50}. The magnetic moments of the Mn_I and Mn_{II} atoms in the central layer are about -3.1 and 2.3 μ_B , respectively. One can see that the magnetic moments of the interfacial Mn_I or Mn_{II} atoms next to the MgO for the Mn_I-Ga or Mn_{II}-Mn_{II} terminations are enhanced to -3.55 μ_B and 2.79 μ_B , respectively, compared to their bulk values due to the *O/p*-Mn/*d* hybridization. In contrast, the two neighboring Ga and O ions in the Mn_IGa/MgO interface tend to repulse each other without any overlapping of electron localization, leading to the rough interfaces as shown in Fig. 1. Notably, the average magnetic moments of the interfacial Mn_{II} atoms next to the Ir cap are dramatically reduced to the values of 1.86 and 1.42 μ_B for the 3ML and 1ML Ir cap, respectively. The underlying mechanism for such moment reduction is the change of the spin-polarized projected density of states (DOS), shown in Fig.3 (a), on the interfacial Mn_{II} next to Ir compared to those of the central Mn_{II}. More specifically, there is a decrease of the occupied majority-spin Mn_{II}-derived DOS compared to those of the central Mn_{II} layer due to the significant hybridization of the Mn_{II}-derived d_{yz} - and d_{z^2} -states with the corresponding interfacial Ir/*d*-derived states. In contrast, there is small change of the minority-spin Mn_{II}-derived states (primarily of d_{xy} character). These two effects lead to the significant reduction of the Mn_{II} moment. The magnetic moment of $\sim 0.1 \mu_B$ of the interfacial Ir atom for the Ir(1)/Mn₃Ga/MgO trilayer is much smaller than that of 0.7 μ_B in the Ir(1ML)/FeCo/MgO, indicating a stronger hybridization effect in the Ir/Mn₃Ga interface^{43,44}. On the other hand, the emergence of magnetism on the Ir atoms in the Ir(3)/Mn₃Ga(5)/MgO(5) heterostructures can be attributed to the proximity effect as the freestanding 3ML Ir is nonmag-

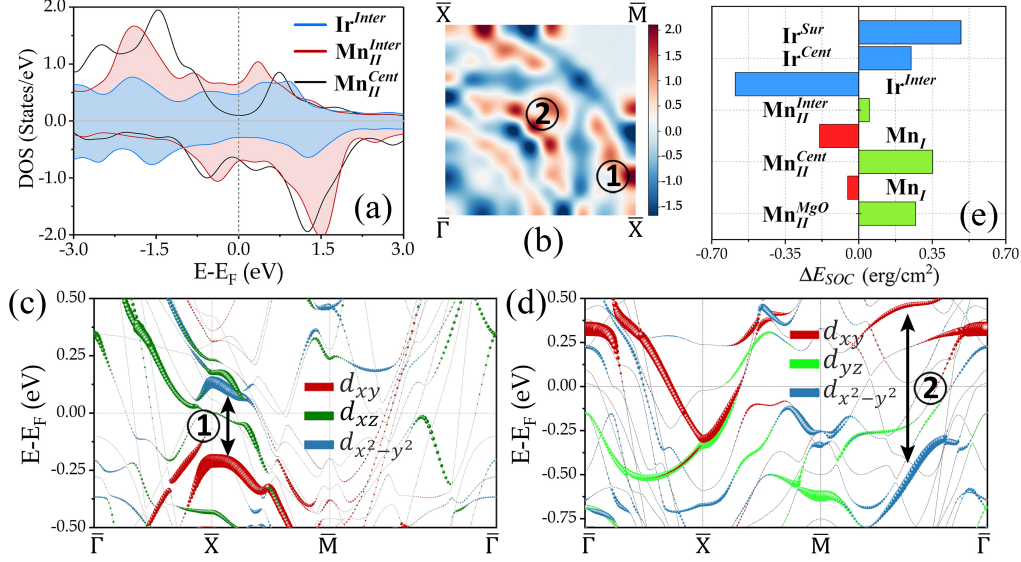

FIG. 3: (a) Atom-resolved spin-polarized DOS for the interfacial Mn_{II} , central Mn_{II} , and interfacial Ir atoms of the Mn_{II} - Mn_{II} -terminated interface of the $\text{Ir}(3)/\text{Mn}_3\text{Ga}(5)/\text{MgO}(5)$ heterostructure. (b) \mathbf{k} -resolved MCA, $\text{MCA}(\mathbf{k})$ (in erg/cm^2) in the 2D BZ. Energy- and \mathbf{k} -resolved distributions of the d -orbital character of (c) minority-spin and (d) majority-spin bands along the symmetry directions for the interfacial Mn_{II} atom. Numerals in panels (b)–(d) refer to BZ \mathbf{k} -points where the MCA is large. (e) Average layer-resolved SOC energy differences, ΔE_{SOC} , per Mn or Ir atom.

TABLE I: Values of the MCA (in erg/cm^2), calculated from differences in total energy, for the (a) Mn_I -Ga- and (b) Mn_{II} - Mn_{II} -terminated interfaces of the $\text{Ir}(n)/\text{Mn}_3\text{Ga}(5)/\text{MgO}(5)$ heterostructure, for different Ir-cap thickness (in ML). The MCA values in brackets are calculated using the force theorem.

Ir thickness (ML)	Mn_I -Ga-termination	Mn_{II} - Mn_{II} -termination
1	-1.78 (-1.70)	24.75 (24.75)
3	-0.14 (-0.14)	2.65 (2.61)
5	-0.09 (-0.09)	-0.97 (-0.96)
7	1.16 (1.17)	-1.77 (-1.78)

netic.

Table I lists values of the MCA (calculated from total energies) for the (a) Mn_I -Ga- and (b) Mn_{II} - Mn_{II} -terminated interfaces of the $\text{Ir}(n)/\text{Mn}_3\text{Ga}(5)/\text{MgO}(5)$ heterostructure for different Ir-cap thickness (in ML). The calculations reveal that the Mn_I -Ga-terminated interface overall favors an in-plane magnetization orientation for $n \leq 3$, while the Mn_{II} - Mn_{II} -terminated interface yields an out-of-plane orientation. Furthermore, the latter heterostructure with a single Ir cap yields a colossal PMA of $24.75 \text{ erg}/\text{cm}^2$ which can be attributed to the large SOC constant of the magnetic Ir overlayer, similar to that of the $\text{Ir}(1)/\text{FeCo}/\text{MgO}$ system.⁴³ In addition, we have also employed the force theorem where²⁰ $\text{MCA} = \sum_{\mathbf{k}} \text{MA}(\mathbf{k})$ to calculate the termination-dependent MCA. The \mathbf{k} -resolved $\text{MCA}(\mathbf{k}) \approx \sum_{n \in \text{occ}} [\varepsilon(n, \mathbf{k})^{[100]} - \varepsilon(n, \mathbf{k})^{[001]}]$ in the 2D Brillouin zone (BZ). Here, $\varepsilon(n, \mathbf{k})^{[100]([001])}$ are the eigenvalues of the Hamiltonian for magnetization along the $[100]$ ($[001]$) direction. The MCA values calculated from the force theorem, also listed in brackets in Table I, agree well with those

obtained from total energy calculations. Besides, it should be noted that the MCA decreases monotonically with increasing Ir cap thickness ($n = 5, 7$) for the Mn_{II} - Mn_{II} termination while it shows an opposite behavior for the Mn_I -Ga termination. Since thicker Ir caps ($n > 3$ ML) yield MCA values $< 2 \text{ erg}/\text{cm}^2$, throughout the remaining study we focus only on the configurations for $n \leq 3$.

The calculated \mathbf{k} -resolved $\text{MA}(\mathbf{k})$ for the Mn_{II} - Mn_{II} -terminated interface for the 3ML-Ir cap is shown in Fig.3 (b). The origin of the hot \mathbf{k} spots, 1 and 2, can be understood from the second-order perturbation theory MCA expression, given by⁴⁵

$$\text{MCA} \approx \sum_{l, lmm'} \sum_{\sigma, \sigma'} \sigma \sigma' \xi_{ll}^2 \frac{P_{ll}^{lm\sigma} P_{ll}^{l'm'\sigma'}}{E_u^\sigma - E_o^{\sigma'}} \Delta L_{l, mm'}, \quad (1)$$

where

$$\Delta L_{l, mm'} = |\langle lm | \hat{L}_z | lm' \rangle|^2 - |\langle lm | \hat{L}_x | lm' \rangle|^2. \quad (2)$$

Here, $\sigma, \sigma' \equiv \pm 1$ denote the electron spin, $\hat{\xi}$ is a diagonal matrix containing the SOC strength, $\hat{L}_{x(z)}$ is the $x(z)$ component of the orbital angular momentum operator, and $P_n^{llm\sigma} = |\langle \Psi_n^\sigma | l m \rangle|^2$ is the Bloch wave amplitude projected on atom l , orbital index lm , spin index σ and $\Psi_n^\sigma(E_n^\sigma)$ is the one-electron occupied and unoccupied spin-polarized Bloch states (energies) of band index n and wave vector \mathbf{k} (omitted for simplicity). Analysis of the orbital-resolved band structures of the interfacial Mn and Ir atoms shows that only the Mn_{II} atoms are primarily responsible for the hot-spots 1 and 2 in the \mathbf{k} -resolved MCA in Fig.3 (b), which yield the dominant contribution to the interfacial MCA. In Fig.3 (c) and (d) we

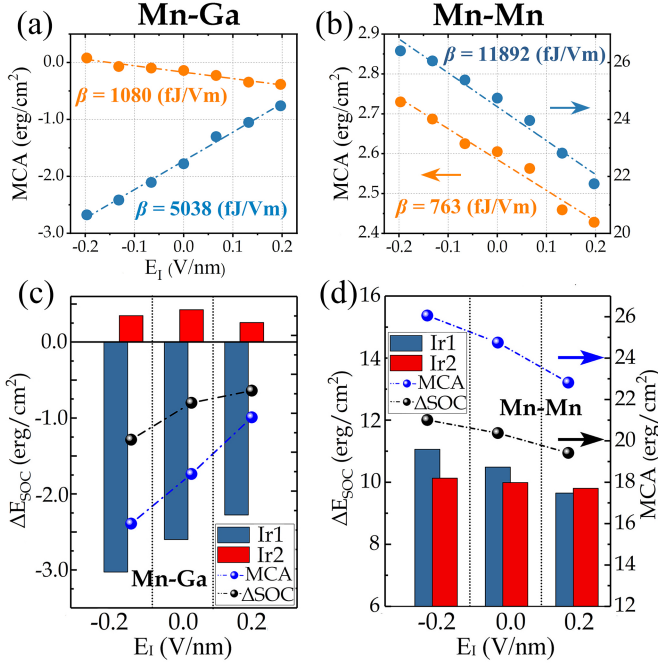

FIG. 4: Magnetic anisotropy as a function of electric field in MgO for the (a) $\text{Mn}_I\text{-Ga}$ and (b) $\text{Mn}_{II}\text{-Mn}_{II}$ terminations for the $\text{Ir}(n)/\text{Mn}_3\text{Ga}/\text{MgO}$ heterostructure with $n = 1$ ML (blue circles) and $n = 3$ ML (orange circles), respectively. Difference in total SOC energies between the in- (\parallel) and out-of-plane (\perp) magnetization orientation, ΔE_{SOC} (blue circles), and MCA energies (black circles) for the (c) $\text{Mn}_I\text{-Ga}$ and (d) $\text{Mn}_{II}\text{-Mn}_{II}$ terminations of the $\text{Ir}(n)/\text{Mn}_3\text{Ga}/\text{MgO}$ heterostructure with $n = 1$ ML, under zero and ± 0.19 V/nm electric field in the insulator. Bar graphs represent the atom-resolved, ΔE_{SOC} , for the two nonequivalent interfacial Ir atoms.

show the energy- and k -resolved distribution of the minority- and majority-spin bands, respectively, of the interfacial Mn_{II} -derived d_{xy} , d_{xz} , and $d_{x^2-y^2}$ states along the high symmetry directions of the 2D BZ. The maximum of $\text{MCA}(k_{\parallel})$ at point 1 (around $\frac{1}{4}\overline{\text{XM}}$) in Fig.3 (b) arises from the SOC between the minority-spin interfacial Mn_{II} -derived occupied d_{xy} states with the unoccupied $d_{x^2-y^2}$ states through the out-of-plane \hat{L}_z operator. The large positive MCA at point 2 (around $\frac{1}{2}\overline{\Gamma\text{M}}$) in Fig.3 (b) arises from the SOC of $\langle d_{xy} | \hat{L}_z | d_{x^2-y^2} \rangle$ of the majority-spin states of interfacial Mn_{II} . In contrast, the negative MCA around $\frac{1}{2}\overline{\Gamma\text{X}}$ is mainly derived from the SOC between minority-spin (majority-spin) occupied d_{xy} (d_{yz}) and unoccupied d_{xz} (d_{xy}) through the in-plane orbital angular momentum, \hat{L}_x . The vanishing $\text{MCA}(k_{\parallel})$ around $\overline{\text{M}}$ in Fig.3 (b) is due to the absence of interfacial Mn_{II} -derived states near the Fermi level.

We have also calculated the atom-resolved SOC energy difference, $\Delta E_{\text{SOC}} = (E_{\text{SOC}}^{\parallel} - E_{\text{SOC}}^{\perp})/2$, for the $\text{Mn}_{II}\text{-Mn}_{II}$ terminated $\text{Ir}(3)/\text{Mn}_3\text{Ga}(5)/\text{MgO}(5)$ heterostructure. Here, $E_{\text{SOC}}^{\parallel}$ and E_{SOC}^{\perp} are the SOC energies with in-plane (\parallel) and out-of-

plane (\perp) magnetization orientation, given by

$$E_{\text{soc}} = \frac{\hbar^2}{2m^2c^2} \left\langle \frac{1}{r} \frac{dV}{dr} \vec{L} \cdot \vec{S} \right\rangle, \quad (3)$$

where $V(r)$ is the spherical part of the effective potential within the PAW sphere. Fig.3(e) shows the average layer-resolved ΔE_{SOC} per Mn or Ir atom. Note that the $\text{MCA} \neq \Delta E_{\text{SOC}}$ is due to the failure of perturbation theory for the Ir atoms which have large SOC constant (≈ 0.45 eV)⁴⁵. However, one can see that the average ΔE_{SOC} of 0.35 erg/cm² per Mn atom for the central $\text{Mn}_{II}\text{-Mn}_{II}$ layer is close to the corresponding bulk value of ~ 0.41 erg/cm². This suggests that the ΔE_{SOC} energies of the bottom three Mn_3Ga layers away from the Ir cap do follow the perturbative treatment in SOC. Since the MCA of the bottom three Mn_3Ga layers is about 1.2 erg/cm², the corrected ΔE_{SOC} for the interfacial $\text{Mn}_3\text{Ga}/\text{Ir}$ layers would be about 1.45 erg/cm², yielding a total MCA of 2.65 erg/cm². These results demonstrate that both interface contributions to the MCA are equally important for thin Mn_3Ga films.

Fig.4 shows the variation of the MCA as a function of the electric field in MgO for the (a) $\text{Mn}_I\text{-Ga}$ - and (b) $\text{Mn}_{II}\text{-Mn}_{II}$ terminated interfaces of the $\text{Ir}(n)/\text{Mn}_3\text{Ga}(5)/\text{MgO}(5)$ heterostructure for both the 1 ML and 3 ML Ir cap, respectively. In the linear regime, the $\text{VCMA} = \Delta(\text{MCA}) = E_{\text{MCA}}(E_{\text{ext}}) - E_{\text{MCA}}(0) = \beta E_I = \beta E_{\text{ext}}/\epsilon_{\perp}$, where β is the VCMA efficiency, E_I is the electric field inside the insulator, and ϵ_{\perp} is the out-of-plane component of the relative dielectric constant tensor of the insulator which depends on strain and the type of the insulator^{20,21}. The results reveal that both the interface termination and the thickness of the iridium cap have a dramatic effect on the magnitude and sign of the VCMA efficiency. For the $\text{Mn}_I\text{-Ga}$ termination β changes from $+5038$ fJ/Vm to -1080 fJ/Vm for the 1 ML and 3 ML Ir cap, respectively, while for the $\text{Mn}_{II}\text{-Mn}_{II}$ termination β changes from -11892 fJ/Vm to -763 fJ/Vm for the 1 ML and 3 ML Ir cap, respectively. These VCMA values are about a factor of 3 to 20 higher compared to the range of about 20-300 fJ/(Vm) of most experimentally reported values for the FeCo-based MTJs.^{32,51} In addition, we find that the VCMA efficiency of the heterostructure with 5ML Ir cap reduces further to 446 (916) fJ/Vm for the $\text{Mn}_{II}\text{-Mn}_{II}$ ($\text{Mn}_I\text{-Ga}$) termination.

In order to understand the microscopic origin of the giant VCMA efficiency of the 1 ML Ir cap, we show in Fig.4 the electric field variation of the difference in SOC energy for the (c) $\text{Mn}_I\text{-Ga}$ - and (d) $\text{Mn}_{II}\text{-Mn}_{II}$ -terminated interfaces, respectively, for the $\text{Ir}(1)/\text{Mn}_3\text{Ga}(5)/\text{MgO}(5)$ system. For comparison, we also show the electric field dependence of the MCA calculated from difference of total energies (blue circles). One can see that $\Delta E_{\text{SOC}} \propto \text{MCA}$ and $d\Delta E_{\text{SOC}}/dE_I \cong d\text{MCA}/dE_I = \beta$. We also display the atom-resolved ΔE_{SOC} of the two interfacial Ir atoms (Ir_1 and Ir_2) on the same layer. The different contributions of interfacial Ir_1 and Ir_2 to the ΔE_{SOC} arise from their asymmetric nature when the magnetization is in-plane. For both types of interface terminations the Ir_1 -resolved ΔE_{SOC} yields the dominant contribution to the total ΔE_{SOC} , due to the larger SOC of the Ir atom ($\xi \sim 451$ meV) compared to that of Mn ($\xi \sim 42$ meV).

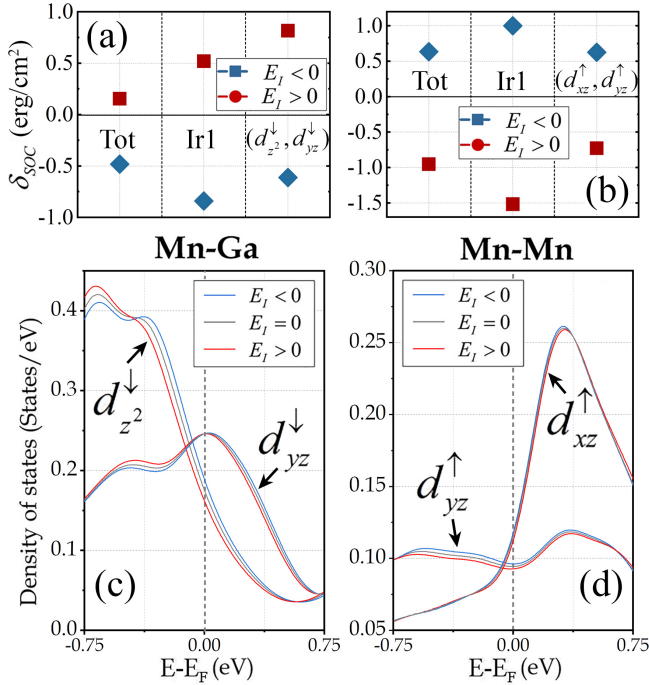

FIG. 5: E-field-induced change of SOC energies, $\delta_{SOC} = \Delta E_{SOC}(\mathbf{E}_I) - \Delta E_{SOC}(\mathbf{E}_I = 0)$, for (a) Mn_I -Ga- and (b) Mn_{II} - Mn_{II} terminations, respectively. We also show the dominant Ir- d -orbital-projected $\langle d_{z^2}^\downarrow | \hat{L}_x | d_{yz}^\downarrow \rangle$ and $\langle d_{xz}^\uparrow | \hat{L}_z | d_{yz}^\uparrow \rangle$ contributions to δE_{SOC} for the two terminations, respectively. The spin-projected DOS of d_{z^2} , d_{xz} , and d_{yz} orbitals for Ir in the heterostructures with the (c) Mn_I -Ga and (d) Mn_{II} - Mn_{II} terminations. The $E_I > 0$ ($E_I < 0$) denotes the applied E-field of +0.19 (-0.19) V/nm in the insulator.

Furthermore, we find a sign reversal of the VCMA efficiency from the Mn_I -Ga- to the Mn_{II} - Mn_{II} termination. In order to understand its origin we have calculated the Ir-5 d orbital-projected contributions to ΔE_{SOC} . In Fig.5 we show the *E-field-induced change* of ΔE_{SOC} , $\delta_{SOC} = \Delta E_{SOC}(\mathbf{E}_I) - \Delta E_{SOC}(\mathbf{E}_I = 0)$, under +0.19 V/nm (red circles) and -0.19 V/nm (blue circles) for the (a) Mn_I -Ga- and (b) Mn_{II} - Mn_{II} -terminated interfaces, respectively, of the Ir(1)/ $Mn_3Ga(5)$ /MgO(5) heterostructure. For the Mn_I -Ga termination we find that the E-field-induced change of SOC energies arises from the SOC of the $d_{z^2}^\downarrow$ - and d_{yz}^\downarrow -derived states of interfacial Ir₁ (as shown in Fig.5(a)) via the in-plane orbital angular momentum operator, \hat{L}_x . The $\langle d_{z^2}^\downarrow | \hat{L}_x | d_{yz}^\downarrow \rangle$ in

turn increases (decreases) under positive (negative) electric field. In sharp contrast, the Mn_{II} - Mn_{II} termination renders the $\langle d_{xz}^\uparrow | \hat{L}_z | d_{yz}^\uparrow \rangle$ dominant which in turn decreases (increases) under negative (positive) E-field.

In addition the electric field has a significant effect primarily on the $d_{z^2}^\downarrow$ and d_{yz}^\downarrow -derived Ir₁ projected density of states (PDOS), shown in Fig. 5 (c) and (d) for the Mn_I -Ga- and Mn_{II} - Mn_{II} terminations, respectively, of the Ir(1 ML)/ $Mn_3Ga(5)$ /MgO(5) heterostructure. For the Mn_I -Ga termination the Ir- $d_{z^2}^\downarrow$ - and Ir- d_{yz}^\downarrow -derived DOS shift downward in energy with increasing electric field, leading to the reduction of the number of occupied d_{z^2} and unoccupied d_{yz} states near the Fermi level. Consequently, the dominant contribution of the in-plane orbital angular momentum, $\langle d_{z^2}^\downarrow | \hat{L}_x | d_{yz}^\downarrow \rangle$, in Eq. (2) decreases leading to an increase of the MCA. In contrast, for the Mn_{II} - Mn_{II} termination the Ir- d_{xz}^\uparrow occupied DOS shift downward in energy with increasing electric field leading to a decrease of the out-of-plane orbital angular momentum matrix element, $\langle d_{xz}^\uparrow | \hat{L}_z | d_{yz}^\uparrow \rangle$, and hence a negative VCMA coefficient.

In summary, *ab initio* electronic structure calculations have been employed to investigate the electric field modulation of magnetism of ultrathin heterostructures based on the ferrimagnetic Mn_3Ga compound. The Ir cap induces large PMA for the Mn-Mn interface termination which, however, changes to in-plane magnetization orientation for the Mn-Ga-terminated interface. In addition to the termination type, the number of Ir layers also shows significant effect on the MCA values of the trilayer structures, leading to the spin reorientation. We predict record-high VCMA coefficients exceeding the required 1000 fJ/(Vm) threshold, whose magnitude and sign depends dramatically on the interface layer termination and Ir cap thickness. We have elucidated that the atomistic mechanism is the electric-field-induced shifts of SOC energies of the Ir/ d -orbitals with different orbital angular momentum symmetries. We hope that these predictions will rekindle experimental interest in the search for Heusler ferrimagnets for the next-generation of non-volatile and ultralow power MeRAM devices.

We would like to thank Farzad Mahfouzi for useful discussions. The work is supported by NSF Grant No. ERC TANMS-116050. Q. S was partially supported by the U.S. Army under Grant No. W911NF-15-1-0066.
