An inelastic neutron scattering study of the spin waves corresponding to the stripe antiferromagnetic order in insulating Rb_{0.8}Fe_{1.5}S₂ throughout the Brillouin zone is reported. The spin wave spectra are well described by a Heisenberg Hamiltonian with anisotropic in-plane exchange interactions. Integrating the ordered moment and the spin fluctuations results in a total moment squared of $27.6 \pm 4.2 \mu_B^2$ /Fe, consistent with S ≈ 2 . Unlike XFe₂As₂ (X = Ca, Sr, and Ba), where the itinerant electrons have a significant contribution, our data suggest that this stripe antiferromagnetically ordered phase in Rb_{0.8}Fe_{1.5}S₂ is a Mott-like insulator with fully localized 3*d* electrons and a high-spin ground state configuration. Nevertheless, the anisotropic exchange couplings appear to be universal in the stripe phase of Fe pnictides and chalcogenides.

Superconductivity emerges in the vicinity of antiferromagnetism (AFM) in both copper-based and high-transition iron-based temperature $(high-T_c)$ superconductors $^{1-4}$. However, the AFM in the cuprate high- T_c and iron-based superconductors could have different origins. The parent compound of the copper oxide superconductors is a Mott insulator with S = 1/2local moments⁵. In the iron pnictides, the parent compounds are bad metals with multiple bands crossing the Fermi level. The stripe AF ordering wavevectors coincide with the wave vectors connecting the centers of the electron and hole Fermi surfaces⁶. In fact many view the AF order as due to the Fermi surface nesting.

From a localized point of view, with 6 electrons in the iron 3d orbitals of Fe²⁺, the maximum total spin is S = 2. This spin state can be realized when the Hund's rule coupling energy, J_H , dominates over the crystal-field splitting associated with the Fe M_4 (M = pnictigens or chalcogens) structural unit. On the other hand, a crystal field splitting, Δ_{CF} , comparable to the Hund's coupling J_H can lead to an intermediate-spin S = 1 state. In the large crystal field extreme, the $3d^6$ ions of Fe²⁺ will form a low-spin singlet S = 0 state⁷⁻⁹. In the presence of itinerant carriers the spin must be less than S = 2 due to charge fluctuations. Thus, the observation of S = 2 for Fe²⁺would require the system to be predominately localized. Not surprisingly, the various values of ordered moments observed in different iron-based materials have been interpreted in terms of both the local moment picture and the itinerant carrier picture^{7–13}. As to the value of the fluctuating local moment, inelastic neutron scattering experiments revealed an increase of S from S \approx 1 at 10 K to S \approx 3/2 at 300 K for Fe_{1.1}Te and a constant S = 1/2 for BaFe₂As₂^{14–16}. In addition, an X-ray emission spectroscopy study was interpreted to imply that the iron spin-state varied between S = 0 and 2 in the rare-earth doped Ca_{1-x}RE_xFe₂As₂ as a function of temperature¹⁷. These findings suggest that the magnetism of the iron pnictides and chalcogenides should be understood from a point of view where both itinerant carriers and local moments coexist.

Recently, the discovery of 30 K superconductivity in the $A_{0.8}$ Fe_ySe₂ (A = alkali metal) materials generated a great deal of research activities due to the lack of the Fermi surface nesting conditions necessary for the itinerant understanding of superconducting pairing¹⁸. Interestingly, a stripe AF order with a rhombic iron vacancy order [Fig. 1 (a,b)] was recently discovered in K_{0.81}Fe_{1.58}Se₂ and Rb_{0.8}Fe_{1.5}S₂, which are insulating compounds in proximity to the superconducting phase in this iron chalcogenide family. The stripe AF orders in these materials have strikingly similar Néel temperatures of $T_N = 280$ K and 275 K, respectively, and moment size of $M = 2.8 \pm 0.5 \mu_B^{19,20}$. More importantly, this stripe AF order has the same structure as the ubiquitous magnetic order in the parent phases of iron pnictides, and has

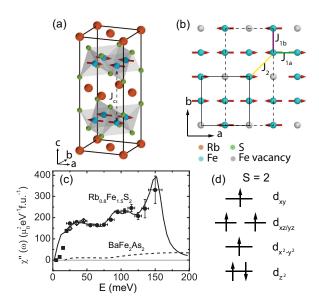

FIG. 1: (color online). Three- (a) and Two- (b) dimensional structures of the stripe AF order with rhombic iron vacancy order in Rb_{0.8}Fe_{1.5}S₂. We use the orthorhombic unit cell as shown by the solid square in (b) with lattice parameters of a = 5.58 Å, b = 5.39 Å, and c = 13.889 Å. The wave vector Q is defined as $Q = [H, K, L] = (2\pi H/a, 2\pi K/b, 2\pi L/c)$ in reciprocal lattice units (r.l.u). The dashed rectangle is the real magnetic unit cell. (c) Dynamic susceptibility $\chi''(\omega)$ as a function of energy with $E_i = 35$ (\blacksquare), 170 (\diamond), and 250 (\bullet) meV at 8 K. The solid line is computed by the model discussed in the text. The dashed line is the dynamic susceptibility of BaFe₂As₂ from Ref.¹⁵. (d) A candidate for the high-spin ground state configuration of the stripe AF order⁷.

hence been proposed as a candidate parent compound for the superconducting phase in $A_{0.8}$ Fe_ySe₂^{19,21}. However, the previous reports on the stripe AF order always showed a mesoscopic interdigitation of the stripe AF order with a robust block AF phase with a $\sqrt{5} \times \sqrt{5}$ iron vacancy order^{19,20}. Therefore, it is very important to understand the nature of this magnetic order by quantitatively characterizing the spin waves in the pure stripe AF phase.

In this paper, we report inelastic neutron scattering studies of the spin wave excitations of the stripe AF order in insulating $Rb_{0.8}Fe_{1.5}S_2$. Only the spin excitations associated with the stripe AF order are observed in our experiment, suggesting a nearly 100% stripe AF order volume fraction. In the presence of iron vacancy order, there are six iron atoms per magnetic unit cell. Hence, one expects three doubly-degenerate spin wave branches. The first acoustic and the second optical branches are observed clearly in both momentum and energy scans in our experiment. The third branch is flat in momentum space and can only be observed by scans in energy. By fitting the spin excitation spectrum to a Heisenberg Hamiltonian with spatially anisotropic exchange couplings $(SJ_{1a} = 42 \pm 5, SJ_{1b} = -20 \pm 2,$ $SJ_2 = 17 \pm 2, SJ_c = 0.29 \pm 0.05$ and $SJ_s = 0.09 \pm 0.02$

meV), all of the branches of the spin excitations can be accurately described. Furthermore, the total dynamic spin fluctuation moment spectrum is calculated to be $\langle m \rangle^2 \approx 20 \mu_B^2/\text{Fe}$, similar to that in the block insulating AF Rb_{0.89}Fe_{1.58}Se₂²², revealing the spin S = 2. Knowing that the stripe AF order is an insulator with a large charge gap (~ 1 eV)²³, the spin S = 2 suggests that all Fe 3*d* electrons are fully localized.

Our experiments were carried out on the MAPS timeof-flight (TOF) chopper spectrometer at the Rutherford-Appleton Laboratory, Didcot, UK, and the BT-7 thermal triple-axis spectrometer at the NIST Center for Neutron Research, Gaithersburg, USA. We coaligned 1.5 grams of single crystals with a mosaic of 1.5° full width at half maximum for the two experiments. For the TOF experiment at MAPS, we aligned the c axis of the sample parallel to the incident beam at energies of E_i = 35, 80, 170 and 250 meV at 8 K. The intensities were normalized to absolute units by vanadium incoherent scattering. For the low energy neutron scattering measurements performed at BT-7, we fixed the final energy at 14.7 meV, with horizontal collimations of open-80'-S-80'-120', where S = sample, and two pyrolytic graphite filters after the sample²⁴. Uncertainties where indicated represent one standard deviation.

We show spin excitations in the [H, K] plane at various energies in Fig.2 (a-e). The spin excitations stem from the AF wave vectors, disperse outwards and separate into two arcs at 65 ± 5 (this notation represents the signal averaged over 60 < E < 70 meV) and 75 ± 5 meV. At the energy of 110 ± 9 meV, the wave vectors rotate 90° .

To describe the spin waves in Rb_{0.8}Fe_{1.5}S₂, we employed a Heisenberg model with in-plane nearest- (J_{1a}, J_{1b}) , and next-nearest- (J_2) neighbor exchange couplings, together with the coupling between layers, J_c , as shown in Fig. 1 (a) and Fig. 1 (b), and the single ion anisotropy term, J_s . The Hamiltonian can be written as:

$$\hat{H} = \frac{J_{r,r'}}{2} \sum_{r,r'} \mathbf{S}_{\mathbf{r}} \cdot \mathbf{S}_{\mathbf{r}'} - J_s \sum_{r} (\mathbf{S}_{\mathbf{r}}^{\mathbf{z}})^2, \qquad (1)$$

where $J_{r,r'}$ are the effective exchange couplings and (r, r')label the iron sites²⁵. The spin wave excitation spectrum can be expressed analytically by solving Eq. (1) using the linear spin wave approximation^{11,13,16,22}. We performed resolution convoluted fits to the time-of-flight data using the Tobyfit program²⁶. From the best fit to the experimental data, the parameters were determined to be $SJ_{1a} = 42 \pm 5$, $SJ_{1b} = -20 \pm 2$, and $SJ_2 = 17 \pm 2$ meV, and for computational convenience an energy independent damping $\Gamma = 7 \pm 2$ meV. The widths of the spin wave peaks in H and K were close to being instrumental resolution limited as expected for an insulator; this also holds true for $K_{0.81}$ Fe_{1.58}Se₂^{27,28}. The simulations with the fit parameters at the identical energies of Fig. 2 (a-e) are presented in Fig. 2 (f-j).

To compare quantitatively the experimental data with the model, we plot cuts along the [H, 0] and [1, K] directions and compare the cuts with the best fits for a wide

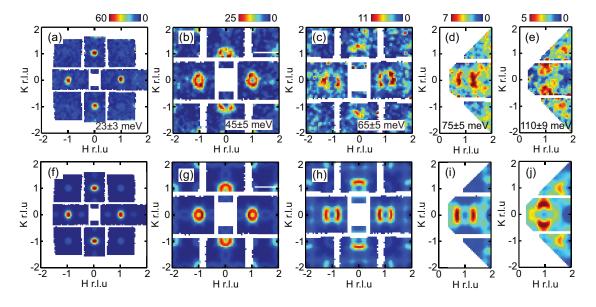

FIG. 2: (color online). Constant energy slices in the [H, K] plane of the spin waves averaged at energies of (a) 23 ± 3 meV with $E_i = 80$ meV, and (b) 45 ± 5 , (c) 65 ± 5 , (d) 75 ± 5 , (e) 110 ± 9 meV with $E_i = 250$ meV, all at 8 K. (f-j) Simulations of spin excitations at the identical energies as in (a-e) using the exchange couplings from the best fits to the experimental data. The simulations were convoluted with the instrumental resolution. The color bar is the same for each energy transfer in units of $mbarnSr^{-1}meV^{-1}f.u.^{-1}$.

range of energies in Fig. 3. The fits are in good agreement with the experimental data at all energies. The small discrepancy near Q = (2,0) is due to an acoustic phonon. The weaker and flatter cut along the [1, K] direction at 65 ± 5 meV in Fig. 3 (g) and the cut along the [H, 0] direction at 110 ± 9 meV in Fig. 3 (d) are consistent with the splitting of the first branch along the [H, 0] direction and the 90° rotation of the second branch.

Fig. 4 (a) and Fig. 4 (b) show the dispersion relations along the [H, 0] and [1, K] directions with $E_i = 250$ meV at 8 K, respectively. The spin excitations from the second twin at Q = (0.5, 0), E = 25 meV in Fig. 4 (a) and the second branch of spin excitations at energies between 90 and 120 meV in Fig. 4 (b) can be observed. The dispersion of the spin excitations extracted from extensive constant energy cuts and Q cuts, together with the results of simulations with the best fit parameters are plotted in Fig. 4 (c) and Fig. 4 (d). Three branches of spin excitations can be seen. We tried to fit the dispersions in $Rb_{0.8}Fe_{1.5}S_2$ with the parameters obtained for $K_{0.81}$ Fe_{1.58}Se₂²⁷. The dispersions of the first branch along the [H, 0] and [1, K] directions were matched very well, but the second branch along the [1, K] direction deviated from the experimental data[see supplementary information].

In order to determine the exchange coupling between layers, J_c , and the single-ion anisotropy term, J_s , we measured the *L*-modulation of the low energy spin excitations at 2 K. The measurements show that a gap in the spin excitations opens up below $\Delta = 6$ meV and that J_c only affects the spin excitation spectrum below 15 meV [Fig. 4 (e)]. By fitting the *L*-modulated spin excitation spectrum, we determined $SJ_c = 0.29 \pm 0.05$ and $SJ_s = 0.09 \pm 0.02$ meV. The temperature dependence of the spin gap was also studied and is presented in Fig. 4 (f). The spin gap remained sharp right up to the phase transition. The scaled magnetic order parameter is plotted along with the temperature dependent spin gap. The evolution of the spin gap with temperature follows the trend of the AF order, in agreement with the behavior observed in K₂NiF₄, a quasi-two-dimensional (2D) Heisenberg AF insulator²⁸.

To unveil the spin state in the stripe AF order of $Rb_{0.8}Fe_{1.5}S_2$, we examined the sum rule of the magnetic neutron scattering. One can calculate the total fluctuating moment squared $\langle \mathbf{m}^2 \rangle$ by integrating the susceptibility $\chi''(\mathbf{q},\omega)$ over the band width of the spin excitations via

$$\langle \mathbf{m}^2 \rangle = \frac{3\hbar}{\pi} \int_{-\infty}^{+\infty} \frac{\int \chi''(\mathbf{q}, \omega) \mathrm{d}\mathbf{q} / \int \mathrm{d}\mathbf{q}}{\mathbf{1} - \exp(-\hbar\omega/k_B T)} \mathrm{d}\omega.$$
(2)

The total moment sum rule is $M_0^2 = g^2 M^2 + \langle \mathbf{m}^2 \rangle = g^2 S(S+1)$, where g is the Landé g-factor and M is the static moment. Thus the spin S can be extracted^{22,29,30}.

The averaged dynamic susceptibility in a Brillouin zone $\chi''(\omega) = \int \chi''(\mathbf{q}, \omega) \mathrm{d}\mathbf{q} / \int \mathrm{d}\mathbf{q}$ is plotted in Fig. 1 (c). The spin fluctuations in Rb_{0.8}Fe_{1.5}S₂ are obviously stronger than those in BaFe₂As₂. Integrating the dynamic susceptibility through all the spin excitation band width results in 29.7 $\pm 5.5\mu_B^2$ /formula unit (f.u.), and thus $19.8 \pm 3.7\mu_B^2$ /Fe. Taking the ordered moment $M = 2.8 \pm 0.5\mu_B$ into account, the total moment squared per Fe is $27.6 \pm 4.2\mu_B^2$, which, assuming g = 2.0, results

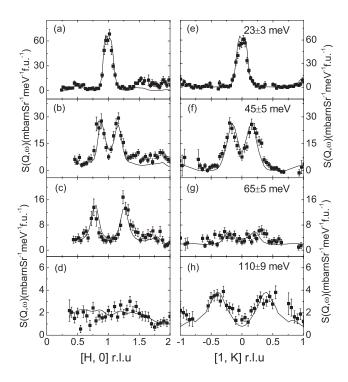

FIG. 3: Constant energy cuts through Q = (1,0) along the [H,0] (a-d) and [1, K] (e-h) directions averaged at energies of 23 ± 3 meV with $E_i = 80$ meV, and $45 \pm 5, 65 \pm 5$, and 110 ± 9 meV with $E_i = 250$ meV, at 8 K. The solid lines are the best fits obtained from the Tobyfit program.

TABLE I: The magnetic exchange couplings and spin states in the stripe AF order of iron pnictides and chalcogenides^{13,16,27}.

Compounds	SJ_{1a}	SJ_{1b}	$SJ_2(\text{meV})$	S	$M(\mu_B)$	$T_N(K)$
$CaFe_2As_2$	50(10)	-6(5)	19(4)	1/2	0.80	173
$BaFe_2As_2$	59(2)	-9(2)	14(1)	1/2	0.87	143
$\mathrm{SrFe}_2\mathrm{As}_2(\mathrm{L})$	31(1)	-5(5)	22(1)	0.30	0.94	220
$\mathrm{SrFe}_2\mathrm{As}_2(\mathrm{H})$	39(2)	-5(5)	27(1)	0.69	0.94	220
$\mathrm{K}_{0.85}\mathrm{Fe}_{1.54}\mathrm{Se}_{2}$	38(7)	-11(5)	19(2)	_	2.8	280
$Rb_{0.8}Fe_{1.5}S_2$	42(5)	-20(2)	17(2)	2	2.8(0.5)	265

in a spin $S = 2.2 \pm 0.2$, which is equal to the upper limit of $24\mu_B^2$ and S = 2 as the Hund's rule result for the 3dFe²⁺ within the error. The results reveal that to within the errors all six 3d electrons of Fe²⁺ are associated with the local moment in the high-spin state. A candidate spin configuration is illustrated in Fig. 1 (d). The fact that the carriers are fully localized in Rb_{0.8}Fe_{1.5}S₂ is consistent with our photoemission measurements on several pieces of single crystals from the same batch. These measurements also reveal a large charge gap below the Fermi energy, suggesting that the stripe AF phase is a Mott-like insulator with the integer spin $S = 2^{21,31}$, rather than a small gap band insulator^{19,20,32}. The Mott localization in Rb_{0.8}Fe_{1.5}S₂ is realized by the presence of the rhombic iron vacancy order, which has enlarged the in-plane Fe-Fe distance, and thus, enhanced the correlation^{21,31}.

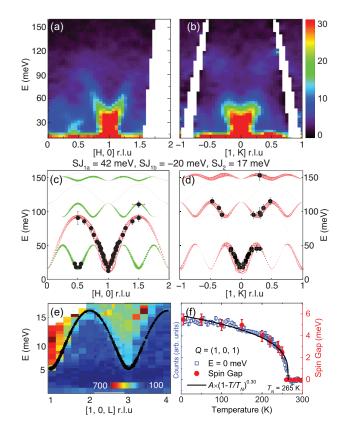

FIG. 4: (color online). (a) Spin excitations along the [H, 0] direction, averaging over $K = \pm 0.2$ r.l.u and (b) along the [1, K] direction, averaging over $H = 1 \pm 0.2$ r.l.u with $E_i = 250$ meV at 8 K. (c, d) The dispersion extracted from experimental data and simulations with the best fit parameters. The red circles are from the first twin, and the green circles are from the second twin[see supplementary information]. The intensity of the simulations of the low energy spin excitations at 2 K and simulations with $SJ_c = 0.29, SJ_s = 0.09$ meV. The intensity is proportional to $\chi''(\mathbf{q}, \omega)$. (f) The temperature evolution of the spin gap measured at Q = (1, 0, 1). The solid line is the result of a fit to the magnetic order parameter (the blue squares) with $A(1 - T/T_N)^{\beta}$, where A is a scaler, $T_N = 265$ K, and $\beta = 0.30$.

Several theoretical methods have been successfully explored to describe the spin waves of the stripe AF order: a combination of density functional theory (DFT) and dynamic mean field theory $(DMFT)^{33,34}$; a Heisenberg model with the anisotropic in-plane exchange couplings $J_{1a}(>0)$, $J_{1b}(<0)$, and $J_2^{11,13,16,27}$; and a Heisenberg model with J_1 , J_2 and a large biquadratic coupling $K^{10,35,36}$. The spin waves of Rb_{0.8}Fe_{1.5}S₂ could be described by either model. In particular the rhombic iron vacancy order which has already broken the C_4 symmetry forms at a temperature higher than 718 K²⁰. The anisotropic J_{1a} and J_{1b} in Rb_{0.8}Fe_{1.5}S₂ could originate from the structural orthorhombicity and the possible orbital ordering³⁷. For the $J_1 - J_2 - K$ model, the exchange couplings are estimated to be $J_1S = (J_{1a} + J_{1b})S/2 =$

 11 ± 3 , $J_2S = 17\pm 2$, and $KS = (J_{1a}-J_{1b})S/4 = 15.5\pm 1.4$ meV³⁵. The biquadratic term could be enhanced by the dynamic fluctuations in the chalcogen height. Distinguishing the two models microscopically is beyond the scope of this work.

We list in Table I the fitted magnetic exchange couplings and measured Fe spin values in a number of stripe phase Fe arsenides and chalcogenides. The Fermi surfaces in these materials vary significantly as do, concomitantly, the conductivity, the ordered moments and the effective spin values. In spite of this, the exchange couplings measured in units of SJ are remarkably universal. This result is both striking and mysterious. It remains to be seen how this relates to the superconductivity of the iron chalcogenides.

In summary, we have studied the spin waves of the pure stripe AF order in $Rb_{0.8}Fe_{1.5}S_2$ over a wide range in reciprocal space and energy. Our inelastic neutron scat-

tering data reveal that even though the stripe AF order has strikingly similar SJ with all the other iron pinctides and chalcogenides, it is an ideal S = 2 Heisenberg antiferromagnet with fully localized moments exhibiting Mott insulator behavior. This indicates the importance of strong electron correlations in the iron-based superconductors, which have thus far mostly been understood from an itinerant point of view. Our results hence form a bridge that connects the iron-based superconductors to the cuprates.
