Magnetic skyrmions are nano-sized topologically protected spin textures with particle-like properties. They can form lattices perpendicular to the magnetic field and the orientation of these skyrmion lattices with respect to the crystallographic lattice is governed by spin-orbit coupling. By performing small angle neutron scattering measurements, we investigate the coupling between the crystallographic and skyrmion lattices in both Cu_2OSeO_3 and the archetype chiral magnet MnSi . The results reveal that the orientation of the skyrmion lattice is primarily determined by the magnetic field direction with respect to the crystallographic lattice. In addition, it is also influenced by the magnetic history of the sample which can induce metastable lattices. Kinetic measurements show that these metastable skyrmion lattices may or may not relax to their equilibrium positions under macroscopic relaxation times. Furthermore, multi-domain lattices may form when two or more equivalent crystallographic directions are favored by spin-orbit coupling and oriented perpendicular to the magnetic field.

I. INTRODUCTION

Magnetic skyrmions are nano-sized topologically protected spin textures with particle-like properties which may form lattices oriented perpendicular to the magnetic field.¹⁻⁷ These Skyrmion Lattices (SkL) were first identified in cubic chiral magnets by Small Angle Neutron Scattering (SANS) inside the A-phase, which is a pocket in the magnetic field (B) - temperature (T) phase diagram just below the critical temperature T_C . Soon after their first observation in MnSi ,¹ skyrmion lattices have been found in other cubic chiral magnets including $\text{Fe}_{1-x}\text{Co}_x\text{Si}$,⁸ FeGe ,⁹ Cu_2OSeO_3 ¹⁰⁻¹² and Co-Zn-Mn alloys.^{13,14} More recently, skyrmions and their lattices have been observed in polar magnets,¹⁵ thin films^{16,17} and at surfaces and interfaces of different atomic layers¹⁸. Skyrmions are topologically stable and can be controlled with extremely small electric currents which frees the path for successful applications in novel spintronic and information storage devices.^{2,3,19,20}

In chiral magnets, the Dzyaloshinskii-Moriya interaction^{21,22} plays a crucial role in stabilizing the helimagnetic order and skyrmion lattices.²³ However, this interaction in itself cannot explain the thermodynamic stability of skyrmion lattices, which has been attributed to additional terms including thermal fluctuations,^{1,7,24} spin exchange stiffness and/or uniaxial anisotropy.²⁵⁻²⁹ The specific orientation of the skyrmion lattice with respect to the crystallographic lattice can be accounted for by higher order spin-orbit coupling terms.¹ In order to describe this orientation dependence, it is convenient to consider the skyrmion lattice as a single domain, long-range ordered state

resulting from the superposition of three helical vectors $\vec{\tau}_i$ separated by 60° .^{12,30} These helices propagate in the plane perpendicular to the magnetic field and lead to the characteristic six-fold symmetric SANS patterns.¹ In MnSi one of the three helices preferentially aligns along the $\langle 110 \rangle$ crystallographic direction. For Cu_2OSeO_3 this orientational preference is along $\langle 100 \rangle$,^{12,31,32} although some SANS measurements seem to indicate that for specific fields and temperatures the $\langle 110 \rangle$ direction is preferred.^{11,33}

Besides this orientational preference, patterns with twelve or more peaks have been observed by SANS and resonant x-ray scattering on Cu_2OSeO_3 .³¹⁻³⁴ These patterns indicate the coexistence of multiple skyrmion lattice domains with different orientations. In fact, such multi-domain states have also been seen by Lorentz Transmission Electron Microscopy in thin films of MnSi and Cu_2OSeO_3 ^{35,36} and by SANS in single crystals of $\text{Fe}_{1-x}\text{Co}_x\text{Si}$.^{8,37} The occurrence of these multi-domain states appears for bulk Cu_2OSeO_3 to be related to the thermal history.^{33,38} In addition, it was proposed that multi-domains are stabilized by magnetic fields applied along directions deviating from the major cubic axes.^{31,32} However, none of these previous studies provides a holistic view on the interrelation between the orientation of skyrmion lattices and the crystallographic lattice, the occurrence of multi-domain lattices and the influence of meta-stabilities induced by different magnetic field histories for all cubic chiral magnets.

In the following we fill this gap by studying the skyrmion lattice orientation with respect to the crystallographic lattice and the occurrence of multi-domain lattices in both the insulator Cu_2OSeO_3 and the archetype

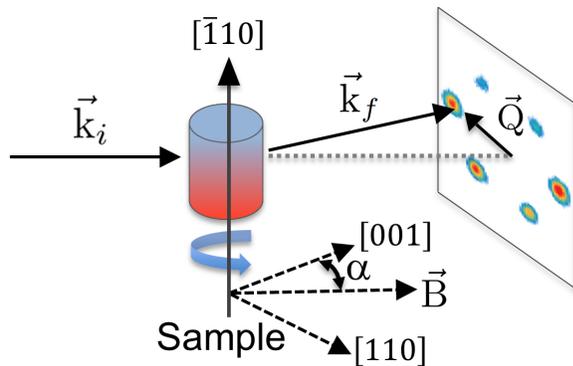

FIG. 1. Schematic representation of the experimental set-up. SANS measurements were performed with the magnetic field applied parallel to the incoming neutron beam with wave-vector \vec{k}_i . The sample was aligned with the $[1\bar{1}0]$ crystallographic direction vertical and rotated around its vertical axis such that the magnetic field is applied along different crystallographic directions. The angle α is defined as the angle between the magnetic field and the $[001]$ crystallographic direction in the horizontal plane, implying that $\alpha = 0^\circ$ corresponds to $\vec{B} \parallel [001]$ and $\alpha = 90^\circ$ to $\vec{B} \parallel [1\bar{1}0]$. The wave-vector \vec{k}_f of the scattered neutron beam and the scattering vector \vec{Q} are also indicated.

chiral magnet MnSi. For this purpose, we performed SANS measurements in a way so far not considered. As schematically shown in Fig. 1, the measurements were performed by rotating the sample around its vertical axis, and thus having the magnetic field applied along different crystallographic directions. By rotating the sample both in zero and under field, we study the effect of the magnetic field history on the orientation of the skyrmion lattice with respect to the crystallographic lattice. The results show unambiguously that the orientation of the skyrmion lattice and the occurrence of multi-domain states is primarily governed by the magnetic field direction with respect to the crystallographic lattice. The orientation of the skyrmion lattice with respect to the crystallographic is also influenced by the magnetic history of the sample. The latter can induce metastable orientations of the skyrmion lattice with respect to the crystallographic one that may or may not relax to their equilibrium orientation under macroscopic relaxation times. Furthermore, multi-domain lattices may form when two or more equivalent crystallographic directions are favored by spin-orbit coupling and oriented perpendicular to the magnetic field.

II. EXPERIMENTAL

The SANS measurements on Cu_2OSeO_3 were performed on a single crystal with dimensions of about $5 \times 3 \times 3 \text{ mm}^3$ grown by chemical vapor transport. The sample was aligned with the $[1\bar{1}0]$ crystallographic di-

rection vertical within 3° . The monochromatic SANS instrument PA20 of the Laboratoire Léon Brillouin was used with a wavelength of $\lambda = 0.6 \text{ nm}$, $\Delta\lambda/\lambda = 0.12$ and the detector placed 12.7 m from the sample. The ^3He XY multidetector is made of 128×128 pixels of $5 \times 5 \text{ mm}^2$. The magnetic field was applied parallel to the incoming neutron beam designated by its wave-vector \vec{k}_i using an Oxford Instruments horizontal field cryomagnet.

The MnSi sample is a cubic single crystal with dimensions of about $5 \times 5 \times 5 \text{ mm}^3$ and was already used in a previous experiment.³⁹ The MnSi sample was also aligned with the $[1\bar{1}0]$ crystallographic direction vertical within 5° . The SANS measurements were performed at the time-of-flight instrument LARMOR of ISIS neutron source using neutrons with wavelengths $0.09 \text{ nm} \leq \lambda \leq 1.25 \text{ nm}$. The sample was placed 4.4 m from the detector that consists of 80 8 mm wide ^3He tubes. The magnetic field was applied with a 3D 2T vector cryomagnet along the incoming neutron beam.⁴⁰ In particular, we eliminated the residual field of the cryomagnet by warming up the entire cryomagnet before the experiment.⁴¹

All SANS patterns are normalized to standard monitor counts and background corrected using a high temperature measurement at 60 K for MnSi and 70 K for Cu_2OSeO_3 .

III. RESULTS

A. Cu_2OSeO_3

We first consider the case of Cu_2OSeO_3 and display in Fig. 2(a) and Supplementary Movie 1⁴² a series of SANS patterns measured at $T = 57.4 \text{ K}$ and $B = 0.02 \text{ T}$. The field was applied during the measurements and switched off when the sample was rotated in steps of 5° from $\alpha = 0^\circ$ to 90° . The angle α is defined as the angle between the magnetic field and the $[001]$ crystallographic axis in the horizontal plane, implying that $\alpha = 0^\circ$ corresponds to $\vec{B} \parallel [001]$ and $\alpha = 90^\circ$ to $\vec{B} \parallel [1\bar{1}0]$.

At $\alpha = 0^\circ$, twelve Bragg peaks are found corresponding to two six-peak patterns rotated 30° from each other. This indicates the stabilization of two distinct skyrmion lattice domains with different orientations with respect to the crystallographic lattice. One of these domains has one set of two peaks aligned along $[100]$ while the other domain has two peaks along the $[010]$ direction. The intensity differences between the peaks are most likely due to a small misalignment of the single crystal and/or demagnetization effects that could also cause small differences in domain populations.

When the sample is rotated and α increases, the $[100]$ and $[010]$ directions are no longer perpendicular to the field and the skyrmion lattices can no longer orient along either of these directions. For small values of α , the twelve-peak patterns persist implying that the coexistence of the two skyrmion domains remains energetically favorable. For larger values of α around 45° , the patterns

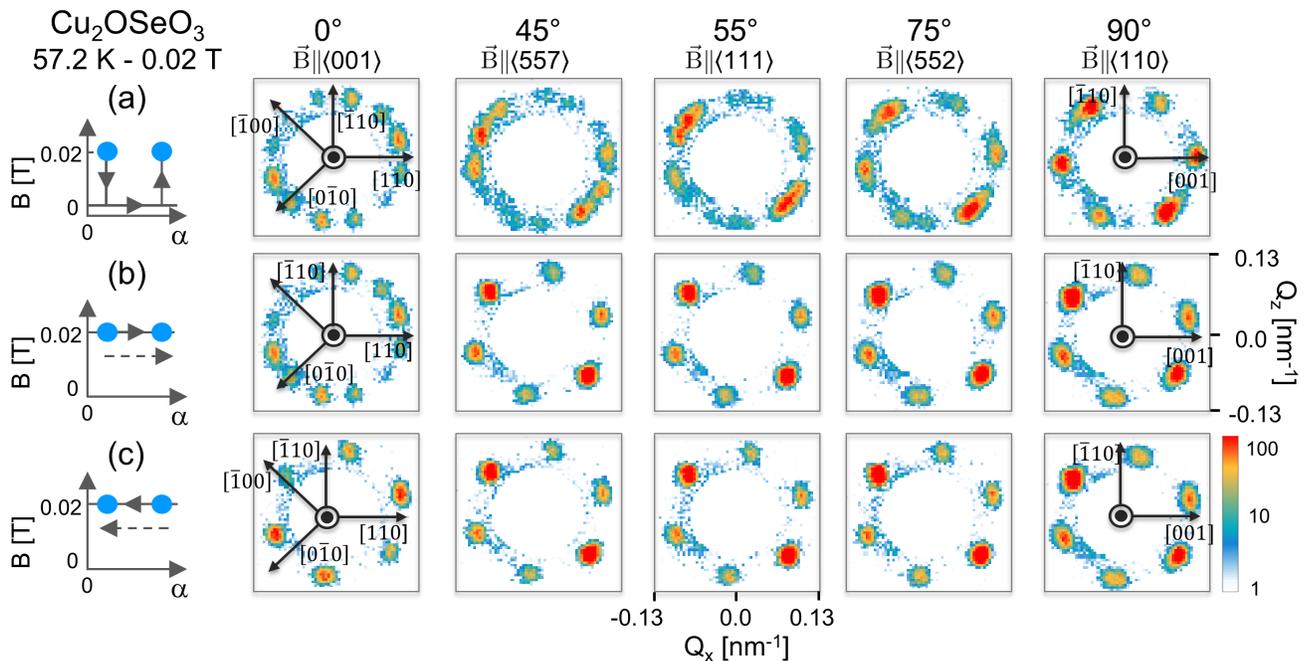

FIG. 2. SANS patterns showing how the skyrmion lattice orients with respect to the crystallographic lattice for different magnetic field orientation for Cu_2OSeO_3 at $T = 57.2$ K and $B = 0.02$ T. The field was applied along different crystallographic directions by rotating the sample in steps of 5° from $\alpha = 0^\circ$ ($\vec{B} \parallel [001]$) to $\alpha = 90^\circ$ ($\vec{B} \parallel [110]$) with (a) the field switched off during rotations, (b) the field continuously on, and (c) rotating the sample backwards in steps of -5° from $\alpha = 90^\circ$ to 0° under field.

seem to indicate 18 peaks. Unfortunately, the resolution of the measurement is not sufficient to unambiguously confirm the existence of these 18 peaks, which would suggest the coexistence of three skyrmion lattice domains as reported elsewhere.³¹

When α is further increased, the third $[001]$ direction approaches the direction perpendicular to the field and the domains gradually merge to one. At $\alpha = 90^\circ$ only six peaks are visible and among them two are aligned along the $[001]$ direction. At this position, the lattice has rotated by 15° with respect to each of the two lattices seen at $\alpha = 0^\circ$.⁴³

A similar rotation scan was performed but this time with the field on during the rotation of the sample. The results, displayed in Fig. 2(b) and Supplementary Movie 2,⁴² show two important differences with respect to the previous case. During this rotation, the scattering from one of the two skyrmion lattice domains is suppressed, whereas the other one is enhanced. Furthermore, the SkL does not reorient for any of the field directions including at $\alpha = 90^\circ$. At this angle the favorable $[001]$ direction is perpendicular to the field, but the skyrmion lattice is oriented 15° away from it and pinned by the field to the position it had at $\alpha = 0^\circ$. This six fold symmetry persists when the sample is rotated back from $\alpha = 90^\circ$ to 0° under magnetic field. As shown in Fig. 2(c), the twelve-fold symmetry is still not recovered at $\alpha = 0^\circ$ where only one skyrmion lattice domain is found. These mea-

surements show that the orientation of skyrmion lattices and the stabilization of multiple domains are strongly influenced by the history of the applied magnetic field direction within the equilibrium skyrmion phase.

B. MnSi

We now consider the case of MnSi and display in Fig. 3(a) a series of SANS patterns measured at $T = 28.4$ K and $B = 0.2$ T after zero-field cooling. For $\alpha = 0^\circ$, i.e. for $\vec{B} \parallel [001]$, two $\langle 110 \rangle$ directions ($[110]$ and $[\bar{1}10]$), that are in MnSi preferred by spin-orbit coupling, are perpendicular to the magnetic field. In contrast to Cu_2OSeO_3 we do not observe twelve peaks, but only six, originating from a single SkL orientation along $[110]$. Six peaks are also seen for $\alpha > 0^\circ$ but this time the SkL aligns along the $[\bar{1}10]$ direction. This orientation, that we name SkL 1, has a scattering pattern that is 30° rotated with respect to the one at $\alpha = 0^\circ$ that we name SkL 2.

The MnSi sample was also rotated from $\alpha = 0^\circ$ to 90° with a magnetic field of 0.2 T on during the measurements and the rotation of the sample. The SANS patterns were recorded every 2° and are presented in Supplementary Movie 3⁴² and a selection in Fig. 3(b). For $0 < \alpha \leq 28^\circ$, the patterns correspond to SkL 2. The patterns qualitatively change for $\alpha > 28^\circ$ and show a superposition of SkL 2 and SkL 1. By further increasing

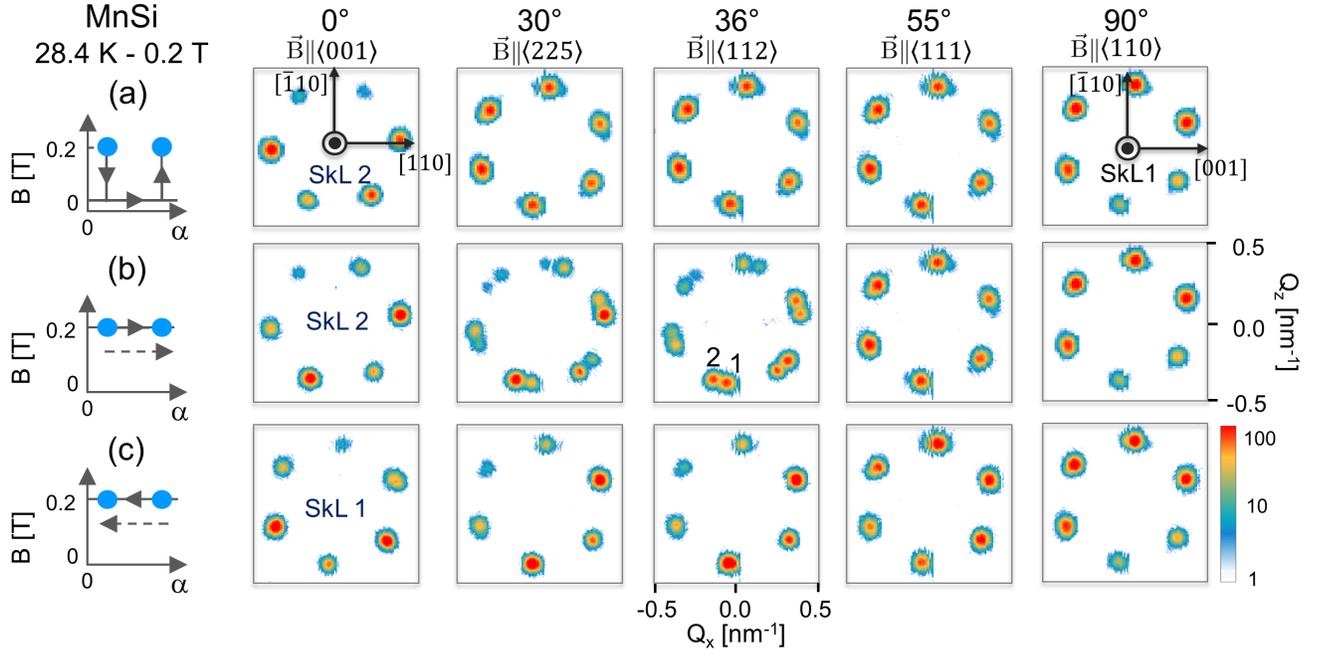

FIG. 3. SANS patterns showing how the skyrmion lattice orients with respect to the crystallographic lattice for different magnetic field orientation for MnSi at $T = 28.4$ K and $B = 0.2$ T. The field was applied along different crystallographic directions (a) after zero field cooling, (b) by rotating the sample in steps of 2° from $\alpha = 0^\circ$ ($\vec{B} \parallel [001]$) to $\alpha = 90^\circ$ ($\vec{B} \parallel [\bar{1}10]$) while keeping the field on during the rotations and (c) by rotating the sample backwards under field from $\alpha = 90^\circ$ in steps of -2° to $\alpha = 0^\circ$.

α , SkL 2 decreases in intensity and totally vanishes at $\alpha \approx 45^\circ$, while at the same time SkL 1 becomes more prominent. As for Cu_2OSeO_3 , the patterns remain the same when the sample is rotated under field back to $\alpha = 0^\circ$. SkL 2 is still not recovered after waiting 30 min at $\alpha = 0^\circ$. These results indicate that in both Cu_2OSeO_3 and MnSi the orientation of the SkL is determined by the magnetic field orientation with respect to crystallographic lattice as well as by the history of the magnetic field (direction) of the sample. They also demonstrate that it is possible to induce metastable skyrmion states in both Cu_2OSeO_3 and MnSi within the thermodynamic equilibrium skyrmion phase.

In order to follow the re-orientation from SkL 2 to SkL 1 as a function of time, we performed fast rotations from $\alpha = 0^\circ$ ($\vec{B} \parallel \langle 100 \rangle$) to $\alpha = 55^\circ$ ($\vec{B} \parallel \langle 111 \rangle$) while keeping the field on. The SANS patterns were recorded continuously using event mode data acquisition. Subsequently, they were processed such that a pattern was obtained for every 3 s. All patterns are displayed in Supplementary Movie 4⁴² and a selection of them are shown in Fig. 4(a). During the first 3 seconds, SkL 1 forms and coexists with SkL 2. Afterwards, the intensity of SkL 2 drops gradually whereas the intensity of SkL 1 increases. After $t \approx 25$ s, the rate at which the intensity of SkL 2 decreases slows down considerably and it takes almost ten minutes for SkL 2 to completely disappear.

A quantitative analysis of this reorientation is provided

by considering the time dependence of the total intensity of all six Bragg peaks of SkL 2. The results are displayed in Fig. 4(b) and show a fast decrease in intensity within the first 25 seconds followed by a slow decay. Therefore, we fitted the data to a superposition of two exponentials:

$$I(t) = a \exp(-t/t_1) + b \exp(-t/t_2) + c. \quad (1)$$

The fit at $T = 28.4$ K provides $a = 3.1 \pm 0.1 \times 10^4$, $b = 1.1 \pm 0.1 \times 10^4$, $c = 2.5 \pm 0.2 \times 10^4$ and the two time constants $t_1 = 11.2 \pm 0.6$ s and $t_2 = 3.0 \pm 0.3 \times 10^2$ s. As such, it shows that the relaxation is governed by two separate processes occurring on the seconds and minutes time-scales, respectively. These processes possibly reflect the movement of (topological) domain walls and/or their pinning to defects of the crystallographic lattice.³⁶ Slow relaxations that originate from multiple processes have also been observed around the A-phase by ac magnetic susceptibility measurements in $\text{Fe}_{1-x}\text{Co}_x\text{Si}$.⁴⁴

The relaxation of skyrmion lattices does not change dramatically in the center of the A-phase. At a lower temperature of 28.1 K, the estimated values are $t_1 = 18.9 \pm 0.4$ s and $t_2 = 2.6 \pm 0.2 \times 10^2$ s. Thus, the characteristic time of the slow relaxation remains almost unchanged, whereas that of the faster process is almost doubled. The relaxation times are very different near the low- and high temperature borders as shown for 27.8 K and 28.7 K in Fig. 4(b). This is not surprising for the

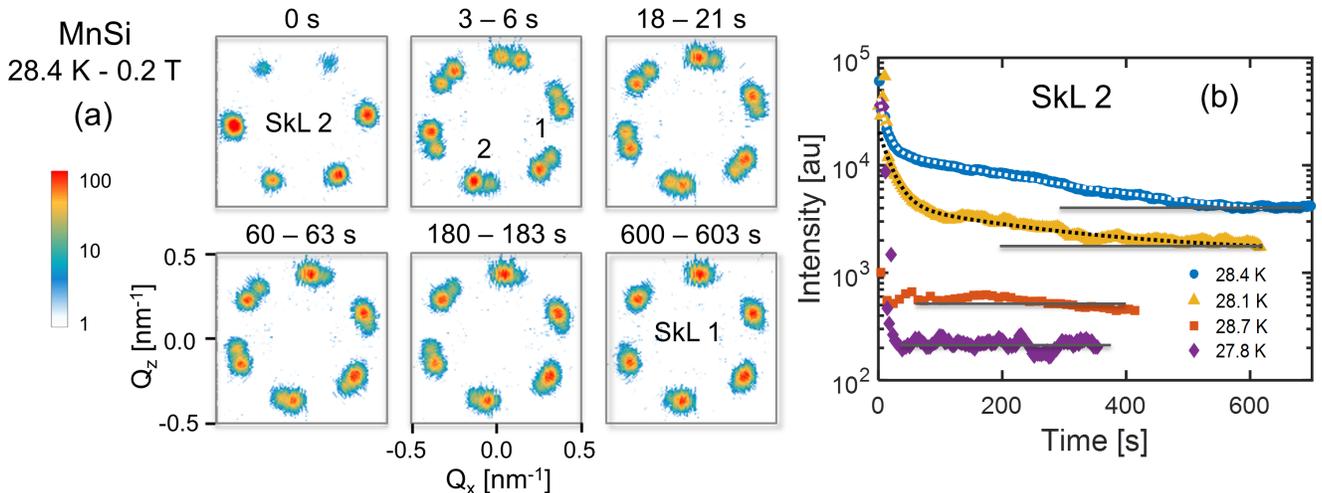

FIG. 4. Time-dependent relaxation of the skyrmion lattice in MnSi when the sample was rotated within 5 s from $\alpha = 0^\circ$ ($\vec{B} \parallel \langle 100 \rangle$) to $\alpha = 55^\circ$ ($\vec{B} \parallel \langle 111 \rangle$) at $B = 0.2$ T. (a) Selection of SANS patterns obtained as a function of time at $T = 28.4$ K. All SANS patterns can be found in Supplementary Movie 4.⁴² (b) The total intensity of SkL 2 as a function of time for several temperatures indicated. The dotted white line for $T = 28.1$ K and the dotted black line for $T = 28.4$ K indicate fits of eq.1 to the data. The horizontal black-lines serve as guides to the eyes and represent the actual base-line intensity.

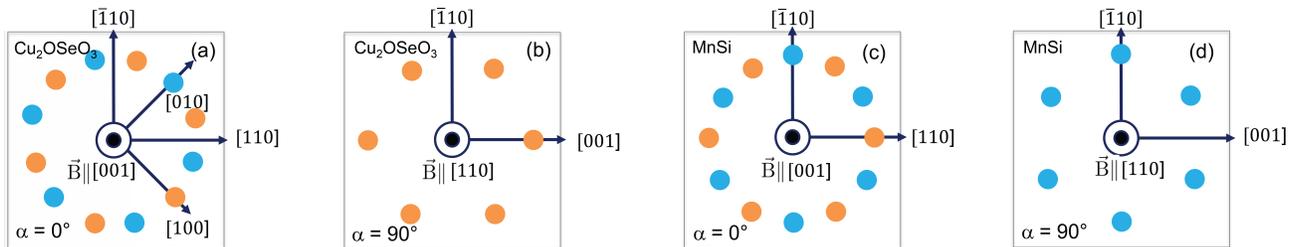

FIG. 5. Schematic illustration of the skyrmion lattice orientations with the minimum energy for (a),(b) Cu_2OSeO_3 where spin-orbit coupling prefers Bragg peaks along $\langle 100 \rangle$ (c),(d) MnSi where it prefers peaks along $\langle 110 \rangle$. The illustrations correspond to the characteristic six Bragg peak scattering pattern of a skyrmion lattice domain seen by SANS. Different colors represent different domains of skyrmion lattices. The magnetic field is applied in the out of plane direction along (a),(c) $\vec{B} \parallel [001]$ ($\alpha = 0^\circ$) and (b),(d) $\vec{B} \parallel [110]$ ($\alpha = 90^\circ$).

high temperature border where it can be attributed to increased thermal fluctuations. The acceleration at the low temperature limit of $T = 27.8$ K may be due to the fact that at this temperature the SkL is stable only for $\vec{B} \parallel \langle 001 \rangle$.⁴⁵ Indeed, we observe that the skyrmion lattice relaxes to the conical phase at this temperature and the SkL is thus not stable for $\vec{B} \parallel \langle 111 \rangle$. This highlights the importance of anisotropy terms.

IV. DISCUSSION AND CONCLUSION

The results presented above show that the skyrmion lattice orients along the crystallographic directions expected from spin-orbit coupling when the samples are zero field cooled. Indeed, based on a Ginzburg-Landau

analysis,^{1,8,11} one expects from the relevant fourth and sixth order spin-orbit coupling terms $\sum_{\tau} (\tau_x^6 + \tau_y^6 + \tau_z^6) |\vec{m}_{\tau}|^2$ and $\sum_{\tau} (\tau_x^4 \tau_y^2 + \tau_y^4 \tau_z^2 + \tau_z^4 \tau_x^2) |\vec{m}_{\tau}|^2$, with \vec{m}_{τ} the Fourier transform of the local magnetization $\vec{M}(\vec{r})$, an alignment of the skyrmion lattice with one of the helical vectors $\vec{\tau} \parallel \langle 100 \rangle$ as for MnSi, or $\vec{\tau} \parallel \langle 110 \rangle$ as for Cu_2OSeO_3 .

Multi-domain lattices may form when several equivalent crystallographic directions, as preferred by spin-orbit coupling, are simultaneously perpendicular to the magnetic field. This is exemplified by the schematic drawings in Fig. 5. Fig. 5(a),(c) show that two domains of skyrmion lattices are expected for both Cu_2OSeO_3 and MnSi for $\alpha = 0^\circ$ and $\vec{B} \parallel \langle 100 \rangle$, where there are two favorable $\langle 100 \rangle$ and $\langle 110 \rangle$ crystallographic directions per-

pendicular to the field. In the other configuration of $\alpha = 90^\circ$ and $\vec{B} \parallel \langle 110 \rangle$ shown in Fig. 5(b),(d), only one $\langle 100 \rangle$ and $\langle 110 \rangle$ crystallographic direction is perpendicular to the field, and hence, only one SkL domain is expected for both chiral magnets. A comparison with experiment shows, however, that multi-domain SkLs are only nucleated in Cu_2OSeO_3 . This is in agreement with literature where, to our knowledge, no stable multi-domain lattice has been reported for bulk single-crystal MnSi so far.

This important difference between Cu_2OSeO_3 and MnSi may be attributed to substantial differences in the most relevant terms in the free energy Landau-Ginzburg functional that contains the Ferromagnetic exchange, DM interaction, Zeeman energy and anisotropy/spin-orbit coupling terms.¹ The most obvious difference is in the coupling to the external field and the Zeeman energy that is almost an order of magnitude stronger for MnSi than Cu_2OSeO_3 . Indeed, the magnetic fields required to stabilize the skyrmion lattice phase are almost an order of magnitude stronger for MnSi than for Cu_2OSeO_3 although the volume magnetizations of both systems are very similar to each other.^{45,46} An additional more subtle but most relevant difference is in the spin-orbit coupling that pins the skyrmion lattice to the crystallographic one. The higher order spin-orbit coupling terms seem to be significantly stronger for MnSi than for Cu_2OSeO_3 . In the later, both the fourth and sixth order terms responsible for this coupling are very weak as pointed out by a previous study.¹¹ Consequently, multi-domain lattices are stabilized in Cu_2OSeO_3 for a wide range of field directions with respect to the crystallographic lattice. A similar case has also been documented for $\text{Fe}_{1-x}\text{Co}_x\text{Si}$ where the coupling of the skyrmion lattice to the crystallographic lattice is likely even weaker.^{8,37} If the spin-orbit coupling is stronger, as is likely the case for MnSi, a different field orientation with respect to the crystallographic lattice has a larger impact on the energy levels of the energy minima. Thus, in MnSi both the stronger Zeeman and spin orbit coupling terms in conjunction with even small sample misalignments, imperfections or demagnetizing fields would raise the degeneracy between different and equivalent skyrmion lattice domains and thus favor a single domain configuration. We therefore conjecture that multi-domain lattices should also exist in MnSi, but only within a very narrow region of field orientations with respect to the crystallographic lattice that has not been realized experimentally until now.

Our results also show that the specific history of the magnetic field (direction) has a significant impact on the SkL orientation. When rotations are performed under field, the multi-domain SkL stabilized for $\vec{B} \parallel \langle 100 \rangle$ in Cu_2OSeO_3 evolves to a single-domain SkL. Upon further rotation, this single domain does not reorient to its zero-field cooled configuration, which one may assume to be

the most energetically favorable one. On the other hand, the skyrmion lattice may reorient under certain conditions for MnSi involving macroscopic relaxation times and metastable multi-domain lattices. Thus for both systems relatively large energy barriers prevent SkLs to reorient to their thermodynamically most favorable state. This is not surprising, as such a reorientation would involve a rearrangement of the magnetic configuration over very large - macroscopic - volumes. These results thus show that it is possible to induce metastable skyrmion states in Cu_2OSeO_3 and MnSi within the thermodynamic equilibrium skyrmion phase.

The stabilization of multi-domain SkL in Cu_2OSeO_3 has previously been attributed to magnetic field directions deviating from the major cubic axes^{31,32} or to the thermal and magnetic history.¹¹ Our results show that specific magnetic field histories can indeed suppress multi-domain lattices. However, in contrast to previous work,^{31,32} we find that multi-domain SkLs can also be stabilized when the field is applied along a major cubic axis such as the $\langle 100 \rangle$ crystallographic direction. The occurrence of multidomain lattices can thus be understood on the basis of symmetry arguments, as illustrated in Fig. 5.

In summary, the results presented above show that the orientation of the skyrmion lattice is primarily governed by the magnetic field direction with respect to the crystallographic lattice, but is also influenced by the magnetic history of the sample. Multi-domain lattices may form when two or more equivalent crystallographic directions are favored by spin-orbit coupling and oriented perpendicular to the magnetic field. These results provide new insights in the factors that stabilize skyrmion lattices and influence their orientation. They shed new light on the puzzle of the occurrence of multiple skyrmion lattice domains, an issue that is of general relevance to chiral magnetism.

ACKNOWLEDGMENTS

The authors wish to express their gratitude to the ISIS and LLB technical support staff for their assistance and are grateful for the kind help of Claudia Decorse with aligning the single crystals. The experiments at the ISIS Pulsed Neutron and Muon Source were supported by a beamtime allocation from the Science and Technology Facilities Council and The Netherlands Organization for Scientific Research (NWO).  - ⁴⁰ The field homogeneity of the 3D cryomagnet, defined as ‘the maximum field error over a 10 mm diameter spherical volume’, is determined by the manufacturer as 0.11 % of the applied magnetic field.
 - ⁴¹ We mounted a field probe on the window of the cryostat to check directly the residual field taking into account its decay with distance. This field probe confirmed the absence of a sizeable residual field. In addition, we made magnetic field scans from negative to positive fields to evaluate the residual field. As the plot of the integrated scattered intensity vs magnetic field was symmetric and centered around one, a sizeable residual field was absent.
 - ⁴² See Supplemental Material at [URL will be inserted by publisher] for the Supplementary Movies.
 - ⁴³ The scattering patterns of this rotation scan are equivalent to those obtained after zero field cooling the sample.
