(Dated: November 30, 2017)

Hydro-kinetic theory of thermal fluctuations is applied to a non-conformal relativistic fluid. Solving the hydro-kinetic equations for an isotropically expanding background we find that hydrodynamic fluctuations give ultraviolet divergent contributions to the energy-momentum tensor. After shifting the temperature to account for the energy of non-equilibrium modes, the remaining divergences are renormalized into local parameters, e.g. pressure and bulk viscosity. We also confirm that the renormalization of the pressure and bulk viscosity is universal by computing them for a Bjorken expansion. The fluctuation-induced bulk viscosity reflects the non-conformal nature of the equation of state and is modestly enhanced near the QCD deconfinement temperature.

I. INTRODUCTION

Ultra-relativistic heavy-ion collisions are a major experimental tool to study nuclear matter in an extremely hot environment. The energy density in heavy ion collisions at the Relativistic Heavy Ion Collider (RHIC) at BNL and the Large Hadron Collider (LHC) at CERN is so high that partonic degrees of freedom are liberated from nucleons and a deconfined quark-gluon plasma (QGP) is formed. The QGP then expands hydrodynamically as a fluid with very small shear viscosity over entropy ratio \( \eta/s = (1–2)/(4\pi) \) [1, 2]. The hydrodynamic paradigm for heavy-ion collisions has been very successful in explaining the various collective flow observables as dynamical response to event-by-event fluctuations of the initial fireball shape [1–5].

Recently, attention has been paid to another source of fluctuations in the hydrodynamic picture, namely, thermal fluctuations [6–12]. Thermal fluctuations are theoretically required by the fluctuation-dissipation theorem. Furthermore, thermal fluctuations play an important role in systems with a small number of particles and are essential near the critical point, which is the focus of the ongoing beam energy scan program at RHIC [13].

A unique feature of hydrodynamic fluctuations in heavy-ion collisions is the rapidly expanding background flow along the beam direction, which at mid-rapidity is often modelled as one dimensional Bjorken flow [14]. The distribution of fluctuations around such evolving background is characterized by a specific wave number scale \( k_* \), where the longitudinal expansion and \((k\text{-dependent})\) relaxation rates balance, and the distribution function approaches a non-equilibrium steady state. In the previous publication, we developed an effective kinetic description for conformal hydrodynamic fluctuations around the characteristic scale \( k_* \) and discussed how to deal with ultra-violet divergences associated with short wavelength fluctuations [15]. Using the hydro-kinetic theory we obtained a universal renormalization of the pressure and shear viscosity in agreement with previous diagrammatic calculations around a non-expanding background [16, 17]. Furthermore, we applied the hydro-kinetic approach to the Bjorken expansion, and found the precise coefficient of the fractional-power-law tail arising due to the out-of-equilibrium distribution of hydrodynamic fluctuations.

In this paper, we consider a relativistic non-conformal fluid, for which the speed of sound \( c_s^2(T) \neq 1/3 \) and the bulk viscosity is finite. The bulk viscosity determines the dissipative correction to the pressure in response to an isotropic expansion or compression and is a measure for scale symmetry breaking. For example, perturbative calculations in a high-temperature QGP show that it is proportional to the square of the scale symmetry breaking factors (the QCD running coupling and finite quark mass) [18]. Also, lattice QCD simulations suggest a correlation between the bulk viscosity and the scale symmetry breaking realized in the equation of state [19]. Spectral sum rules in the bulk channel also indicate some correlation between the bulk viscosity and a non-conformal nature of the equation of state [20–23]. Finally, near the
critical point, the bulk viscosity diverges due to the critical slowing down [24].

In main part of the paper we apply our hydro-kinetic theory to a static system perturbed by an isotropic expansion and compute the response function of the energy-momentum tensor in the bulk channel. We discuss the case of Bjorken expansion in the Appendix A. In a non-conformal fluid the two point correlation function of hydrodynamic fluctuations contributes to the trace of the energy momentum tensor, which gives rise to a renormalization of the bulk viscosity:

\[
\zeta(T) = \zeta_0(T; \Lambda) + \frac{TA}{18\pi^2} \left[ \left( 1 + \frac{3T}{2} \frac{dc_{s0}^2}{dT} - 3c_{s0}^2 \right) \left( \frac{c_{s0}^2 + 2\eta_0}{\zeta_0 + \frac{3}{2}\eta_0} \right)^2 \right. \\
\left. + 4 \left( 1 - 3c_{s0}^2 \right)^2 \frac{\epsilon_0 + p_0}{2\eta_0} \right].
\]  

(1)

Here, Λ is a UV cut-off for the hydrodynamic fluctuations and \( \zeta_0(T; \Lambda) \) is the bare bulk viscosity. The fluctuation contribution to the bulk viscosity is positive and proportional to the scale symmetry breaking factors in the equation of state. It is noteworthy that in order to arrive to eq. (1), the temperature of the background fluid must be shifted depending on the cut-off so as to include the energy of the non-equilibrium hydrodynamic modes (see Sec. III B for details).

The fluctuation induced renormalization in eq. (1) can be used to estimate a lower bound of the bulk viscosity of QCD – see ref. [17] for a similar estimate of the shear viscosity. Very recently the approach was also used to estimate the bulk viscosity of a non-relativistic cold Fermi gas, where the renormalization was obtained with diagrammatic methods [25] (we performed the diagrammatic calculation for the relativistic non-conformal fluid in Appendix B). Using the lattice equation of state for entropy density \( s(T) \) and the speed of sound \( c^2_s(T) \) [26] in eq. (1), we calculate the magnitude of bulk viscosity renormalization by setting \( \zeta_0 = 0 \), and choosing a representative values of the kinematic viscosity, \( \eta/s = 1/4\pi \), and the temperature dependent UV cut-off \( \Lambda = 2T - 4T \) (see Fig. 1). Due to small deviation from scale symmetry at high temperatures the bulk viscosity renormalization is vanishing small for \( T \gg T_c \). However, the degree of non-conformality \( (c_s^2 - \frac{1}{3})^2 \) peaks around the pseudo-critical temperature where the bulk viscosity reaches \( \zeta/s \approx 0.03 \) at \( T_c \sim 150 \) MeV.

The logic of the estimate in Fig. 1 is the following. The physical bulk viscosity \( \zeta(T) \) (which is independent of \( \Lambda \)) arises from two contributions: the fluctuations above \( \Lambda \), which at weak coupling are dominated by single-particle excitations, and the fluctuations below \( \Lambda \), which are described by hydrodynamics. We have only included the hydrodynamic fluctuations here, and thus we expect the physical bulk viscosity to be larger than the estimate shown in Fig. 1.

The organization of this paper is as follows. In Sec. II, we derive the kinetic equations for hydrodynamic fluctuations for an isotropically expanding non-conformal fluid. Then in Sec. III, we compute the fluctuation contributions to the energy-momentum tensor, and discuss the subtle temperature shift. After the temperature shift, we renormalize the energy density, the pressure and the bulk viscosity, and find the finite long time tails for the weak isotropic expansion. The summary of the paper is given in Sec. IV. Finally, in Appendix A we repeat the computation of the temperature shift and the renormalization of hydrodynamic fields for Bjorken expansion. In Appendix B, we give a diagrammatic derivation for the bulk viscosity renormalization, which is consistent with our results by the hydro-kinetic theory.

### II. KINETIC EQUATIONS FOR HYDRODYNAMIC FLUCTUATIONS

In this section we apply the formalism developed in ref. [15] to a non-conformal fluid under isotropic expansion (or compression). We will follow the same procedure to derive the relaxation type equations for the two point correlation functions under the presence of background perturbations.

The governing equations for non-conformal hydrody-
namics with noise are given by [27–29]

\begin{align}
    d_\mu T^{\mu \nu} &= 0, \quad T^{\mu \nu} = T^{\mu \nu}_{\text{ideal}} + T^{\mu \nu}_{\text{visc}} + S^{\mu \nu}, \quad (2a) \\
    T^{\mu \nu}_{\text{ideal}} &= (e + p)u^\mu u^\nu + pg^{\mu \nu}, \quad (2b) \\
    T^{\mu \nu}_{\text{visc}} &= -\eta\sigma^{\mu \nu} - \zeta \Delta^{\mu \nu} \Delta \beta_{\alpha \beta}, \quad (2c) \\
    \sigma^{\mu \nu} &= \Delta^{\mu \rho} \Delta^{\nu \sigma} (d_\rho u_\sigma + d_\sigma u_\rho - \frac{2}{3} g_{\rho \sigma} d_\gamma u^\gamma), \quad (2d) \\
    \Delta^{\mu \nu} &= g^{\mu \nu} + u^\mu u^\nu, \quad (2e)
\end{align}

where \(d_\mu\) denotes a covariant derivative using the “mostly-plus” metric convention. Below we note the divergence of the flow velocity as \(\nabla \cdot u \equiv d_\mu u^\mu\). The variance of the stochastic noise is determined by the fluctuation-dissipation theorem:

\[
    \langle S^{\nu \alpha}(x_1) S^{\alpha \beta}(x_2) \rangle = 2T \left[ \eta \left( \frac{2}{3} \right) \Delta^{\nu \alpha} \Delta^{\mu \beta} \right] \delta(x_1 - x_2), \quad (3)
\]

Differently from the conformal case, both shear \(\eta\) and bulk \(\zeta\) viscosities are now present in the equation of motion and noise correlator.

### A. Background fluid

Dynamics of hydrodynamic fluctuations on a background fluid in a weak isotropic expansion (or compression) is conveniently studied in the reference frame of the fluid. In the comoving frame for the isotropic expansion, the metric is time dependent

\[
    ds^2 = -dt^2 + \frac{1}{h(t)} \left( dx^i dx^i - f(t)^2 \delta_{ij} dx^i dx^j \right), \quad (4)
\]

and the background fluid satisfies

\[
    0 = \dot{e}_0(t) + \frac{3h}{2} (e_0(t) + p_0(t)) + O(h^2), \quad (5)
\]

The second term on the right hand side represents the change of energy density due to the expansion and the associated work done by the pressure. Throughout this paper, \(X_0\) denotes a quantity \(X\) of the background fluid in a perturbed metric \((h \neq 0)\). As discussed previously [15], \(e_0(t)\) and \(p_0(t)\) denote the background energy density and pressure from modes with wavenumbers greater than a cut-off \(\Lambda\). In Sec. III B we detail how \(e_0\) and \(p_0\) are related to the lattice equation of state.

Solving perturbatively in \(h\), the energy density \(e_0(t)\) for the background fluid satisfies

\[
    e_0(t) = \bar{e}_0 - \frac{3h(t)}{2} (\bar{e}_0 + \bar{p}_0) + O(h^2), \quad (6)
\]

where \(\bar{e}_0\) denotes the energy density of the background fluid in an unperturbed state \((h = 0)\). Again, throughout this paper \(X_0\) denotes a quantity \(X\) of the background fluid in an unperturbed state \((h = 0)\).

### B. Evolution of hydrodynamic fluctuations

For the expanding background described by eq. (6), the hydrodynamic fluctuations excited by thermal noise \(\delta e(t, \mathbf{x}) \equiv e(t, \mathbf{x}) - e_0(t)\) and \(\delta \mathbf{g} \equiv (e_0(t) + p_0(t)) \delta \mathbf{e}(t, \mathbf{x})\) evolve according to the following equations in \(k\)-space:

\[
    0 = \partial_t \delta e + ik^i \delta g_i + \frac{3h}{2} (1 + \frac{2}{3} e_0) \delta e, \quad (7a)
\]

\[
    0 = \partial_t g_i + i e_0 \Omega k^i \delta e + \frac{3h}{2} g_i + \gamma_{\sigma 0} (k^j k_0 \delta^j_i - k_i k^j) g_j + \gamma_{\sigma 0} k_k k_j \delta e, \quad (7b)
\]

with noise correlation given by

\[
    \langle \xi_i(t, k) \xi_j(t', -k') \rangle = \frac{2T_0(e_0 + p_0)}{\sqrt{-\det g_{\mu \nu}}} (2\pi)^3 \delta(k - k') \delta(t - t') \times \left[ \gamma_{ij} (k_i k_j - k_j k_j) + \gamma_{ij} k_i k_j \right]. \quad (8)
\]

Here \(\gamma_{\sigma 0} \equiv \eta/(e + p)\) and \(\gamma_{ij} \equiv (\zeta + \frac{4}{3} \eta)/(e + p)\) are kinematic viscosities. Analysis becomes simpler by utilizing a vielbein formalism. We introduce new variables

\[
    G_i = \left( 1 + \frac{1}{2} \Omega(t) \right) g_i, \quad (9a)
\]

\[
    K_i = \left( 1 - \frac{1}{2} \Omega(t) \right) k_i, \quad (9b)
\]

\[
    \Xi_i = \left( 1 + \frac{1}{2} h(t) \right) \xi_i, \quad (9c)
\]

which give \(G_i G_i = g_i g_i\), \(K_i K_i = k_i k_i\), and \(G_i K_j = g^j k_i = g_i k^j\). We define a four component vector \(\phi_a = (c_{ij} \delta e, \bar{G})\) of hydrodynamic fluctuations. The equation of motion for \(\phi_a\) is

\[
    -\dot{\phi}_a(t, k) = i \mathcal{L}_{ab} \phi_b + \mathcal{D}_{ab} \phi_b + \Xi_a + \mathcal{P}_{ab} \phi_b, \quad (10a)
\]

\[
    \mathcal{L} = \left( \begin{array}{cc}
        0 & c_{00} \bar{K} \\
        c_{00} \bar{K} & 0
    \end{array} \right), \quad (10b)
\]

\[
    \mathcal{D} = \left( \begin{array}{cc}
        0 & 0 \\
        \gamma_{00} \left( K^2 \delta_{ij} - K_i K_j \right) + \gamma_{ij} K_i K_j
    \end{array} \right), \quad (10c)
\]

\[
    \mathcal{P} = \hat{h} \left( \frac{3}{2} \left( 1 + \bar{c}_{00} + \frac{\bar{c}_{ij} \delta e}{2 \bar{G}} \right) \right)^2 \left( \begin{array}{c}
        2 \\
        2
    \end{array} \right), \quad (10d)
\]

with noise correlation given by

\[
    \langle \Xi_a(t, k) \Xi_b(t', -k') \rangle = \frac{2T_0(e_0 + p_0)}{\sqrt{-\det g_{\mu \nu}}} \mathcal{D}_{ab} (2\pi)^3 \delta(k - k') \delta(t - t'). \quad (11)
\]

The matrices \(\mathcal{L}\) and \(\mathcal{D}\) originate from ideal and viscous parts of the hydrodynamic equations respectively, while
\( \mathcal{P} \) arises from remaining interactions between the fluctuations and the background fluid. Note that the term \( \propto \frac{\bar{T}_i \, \Delta e^2}{\Delta T_0} \) in \( \mathcal{P} \) derives from the time dependence of \( e_0(T_0(t)) \Delta e \) in \( \phi_1 \). In the kinetic regime, \( \mathcal{L} \) drives the evolution of \( \phi_\alpha \) so that it will be more convenient to analyze eq. (10a) in terms of eigenmodes of \( \mathcal{L} \):

\[
(e_{\pm})_a = \frac{1}{\sqrt{2}} \left( \begin{array}{c}
1 \\
\pm \bar{K}
\end{array} \right), \quad (e_{T})_a = \left( \begin{array}{c}
0 \\
\bar{T}_1
\end{array} \right), \quad (e_{T_2})_a = \left( \begin{array}{c}
0 \\
\bar{T}_2
\end{array} \right).
\]

Here \( \bar{K} \equiv \bar{K}/|K| \), \( \bar{T}_1 \), and \( \bar{T}_2 \) form an orthonormal basis. The subscripts +, - stand for the two sound modes and \( T_1, T_2 \) for the two transverse diffusive modes. The corresponding eigenvalues are \( \lambda_{\pm} = \pm e_\alpha K \) and \( \lambda_{T_1, T_2} = 0 \).

C. Kinetic equations for hydrodynamic fluctuations

The two-point correlation functions of \( \phi_A \equiv \phi_\alpha (e_{\alpha})_a \) with \( A = +, -, T_1, T_2 \) are defined as

\[
\langle \phi_A(t, k) \phi_{A'}(t, -k') \rangle \equiv N_{AB}(t, k)(2\pi)^3 \delta(k - k').
\]

We will determine the equations of motion for \( N_{AB}(t, k) \) using the formalism of ref. [15]. In the rotating wave approximation, the off-diagonal part of the density matrix \( N_{AB} \) can be neglected because of its rapid phase rotation1, while the diagonal part evolves according to

\[
\dot{N}_{AA} = -2D_{AA} \left[ N_{AA} - \frac{T_0(e_0 + p_0)}{\sqrt{-\det g_{\mu\nu}}} \right] + 2P_{AA} N_{AA},
\]

(14)

where we have defined \( D_{AA} \equiv (e_{\alpha})_a D_{ab}(e_{\alpha})_b \) and similarly \( P_{AA} \). The isotropic system does not distinguish the two transverse modes \( T_1 \) and \( T_2 \), and thus we only have two independent kinetic equations: one for the sound modes \( (L = +, -) \), and one for the transverse modes \( (T = T_1 T_2) \). Using the matrices and eigenvectors of the previous section, eq. (14) evaluates to

\[
\dot{N}_L = -\gamma_0 K^2 \left[ N_L - \frac{T_0(e_0 + p_0)}{\sqrt{-\det g_{\mu\nu}}} \right]
- \frac{1}{2} \left( 3\varepsilon_0^2 + 3\bar{T}_0 \frac{\Delta e^2}{\Delta T_0} + 7 \right) N_L,
\]

(15a)

\[
\dot{N}_T = -2\gamma_0 K^2 \left[ N_T - \frac{T_0(e_0 + p_0)}{\sqrt{-\det g_{\mu\nu}}} \right] - 4\bar{h} N_T.
\]

(15b)

The kinetic equations (15a) and (15b) describe how the distribution of fluctuations \( \phi_A \) evolves on the isotropically expanding background. Perturbative solutions of the kinetic equations for \(|h| \ll 1\) take the form

\[
N_{L/T}(t, k) = N_{eq}(t) + \delta N_{L/T}(t, k) + O(h^2),
\]

(16)

where the equilibrium contribution is

\[
N_{eq}(t) = \frac{T_0(e_0 + p_0)}{\sqrt{-\det g_{\mu\nu}}}
\]

\[
\simeq \left[ 1 - (3 + 3\varepsilon_0^2)h(t) \right] T_0(e_0 + p_0),
\]

(17)

and the non-equilibrium correction \( \delta N_{L/T} \) is

\[
\delta N_L(\omega, k) = \frac{i\omega h(\omega)}{-i\omega + \gamma_0 K^2} \bar{C}_{\omega 0} \dot{T}_0(e_0 + p_0),
\]

(18a)

\[
\delta N_T(\omega, k) = \frac{i\omega h(\omega)}{-i\omega + 2\gamma_0 K^2} \bar{C}_{\gamma 0} \dot{T}_0(e_0 + p_0).
\]

(18b)

Here and below we have defined

\[
C_\zeta(T) \equiv 1 + \frac{3T \, \Delta e^2}{2} - 3e_0^2,
\]

(19a)

\[
C_\eta(T) \equiv 1 - 3e_0^2.
\]

(19b)

Note that when the background fluid is scale invariant \( e_0 = 3p_0 \), the corrections \( \delta N_{L/T} \) vanish. Therefore in conformal case, the isotropic expansion or compression does not drive the hydrodynamic fluctuations from the equilibrium distribution \( N_{eq}(t) \) given by eq. (17). For \( k \sim k_* \), the distribution of fluctuations in eq. (18) is not well characterized by the time derivatives of \( h(t) \). However, at large \( k \) by the distribution approaches equilibrium with calculable first derivative corrections2

\[
\delta N_L(t, k) \simeq -\frac{3\bar{C}_{\omega 0} \dot{T}_0(e_0 + p_0)}{\gamma_0 K^2} \nabla \cdot u,
\]

(20a)

\[
\delta N_T(t, k) \simeq -\frac{3\bar{C}_{\gamma 0} \dot{T}_0(e_0 + p_0)}{2\gamma_0 K^2} \nabla \cdot u.
\]

(20b)

It is these corrections \( \propto \nabla \cdot u/K^2 \) which are responsible for the renormalization of the bulk viscosity and the temperature shift described in Sect. III.

III. ENERGY-MOMENTUM TENSOR WITH NONLINEAR FLUCTUATIONS

In this section we compute the non-linear contributions of hydrodynamic fluctuations to the statistically averaged energy momentum tensor \( (T_{\mu\nu}) \). The main difference from the conformal case [15] is additional contributions to the averaged energy density \( (T^00) \), which are absorbed by a shift in the background temperature \( T_0(t, \Lambda) \).

1 \( N_{T_1 T_2} \) has a stationary phase but vanishes due to the rotational symmetry.

2 In the current setup \( \nabla \cdot u = \frac{1}{3} \bar{h} \).
A. Averaged energy-momentum tensor

The averaged stress tensor consists of contributions from the background fluid and from the two-point functions of the hydrodynamic fluctuations:

\[ \langle T^{ij} \rangle = (1 - h(t)) \rho_0 \delta^{ij} - \frac{3}{2} \dot{h}(t) \dot{\zeta}_0 \delta^{ij} + T_{\text{fluct}}^{ij}, \quad (21a) \]

\[ T_{\text{fluct}}^{ij} \approx \frac{1 - h(t)}{\epsilon_0 + p_0} \left[ \left( \frac{G_i(t, x) G_j(t, x)}{2} \right) + \delta^{ij} T_0 \frac{d^2 \rho_0}{d T_0^2} ((c_{a0} \delta e(t, x))^2) \right]. \quad (21b) \]

The energy density fluctuations \( \equiv \langle (c_{a0} \delta e(t, x))^2 \rangle \) originate from the second-order derivative \( \frac{d^2 \rho_0}{d T_0^2} \), which is finite for a non-conformal equation of state. The trace of the stress tensor from the fluctuations is determined by the two-point functions \( N_{T/T} \):

\[ T_{\text{fluct}}^{ii} = \frac{1 - h(t)}{\epsilon_0 + p_0} \int \frac{d^3 k}{(2\pi)^3} \left[ 1 + \frac{3 T_0 \frac{d^2 \rho_0}{d T_0^2}}{2} \right] N_L(t, k) + 2 N_T(t, k). \quad (22) \]

This integral is divergent and is regularized by introducing a cut-off \( \Lambda \) for \( K \) (not \( k \)). Substituting the solution \( (16), \) we write the fluctuating contribution as a sum of two terms

\[ T_{\text{fluct}}^{ii}(t, \Lambda) = T_{N_{eq}}^{ii}(t; \Lambda) + T_{\delta N}^{ii}(t; \Lambda). \quad (23) \]

The first term arises from equilibrium fluctuations \( N_{eq}(t) \) (eq. (17))

\[ T_{N_{eq}}^{ii}(t; \Lambda) \equiv \left[ 1 - h(t) \right] \left( 1 + \frac{T_0 \frac{d^2 \rho_0}{d T_0^2}}{2} \right) = \frac{T_0 \Lambda^3}{2\pi^2}, \quad (24) \]

while the second term arises from the non-equilibrium distribution functions, \( \delta N_{L/T} \) in eq. (18). In frequency space this non-equilibrium contribution reads

\[ T_{\delta N}^{ii}(\omega; \Lambda) \equiv \frac{h(\omega) T_0}{4\pi^2} \left( 1 + \frac{3 T_0 \frac{d^2 \rho_0}{d T_0^2}}{2} \right) \dot{C}_{\zeta 0} f(\omega, \dot{\gamma}_{\zeta 0}, \Lambda) \]

\[ + \frac{h(\omega) T_0}{\pi^2} \dot{C}_{\eta 0} f(\omega, 2 \dot{\gamma}_{\eta 0}, \Lambda). \quad (25) \]

Here we have defined a function

\[ f(\omega, \gamma, \Lambda) \equiv \int_{0}^{\Lambda \to \infty} \frac{dp}{2\pi} \frac{i \omega}{-i \omega + \gamma p^2} \]

\[ = \frac{i \omega \Lambda}{\gamma} - \left( \frac{|\omega|}{\gamma} \right)^{3/2} \frac{\pi}{2\sqrt{2}} (1 + i \text{sgn}(\omega)). \quad (26) \]

Next, we calculate the averaged energy density in a similar manner. It also consists of contributions from the background fluid and from the two-point functions of the fluctuations:

\[ \langle T^{tt} \rangle = e_0 + T_{\text{fluct}}^{tt}, \quad (27a) \]

\[ T_{\text{fluct}}^{tt} = \langle C^2 \rangle \]

\[ = \frac{1}{\epsilon_0 + p_0} \int \frac{d^3 k}{(2\pi)^3} \left[ N_L(t, k) + 2 N_T(t, k) \right], \quad (27b) \]

The contribution from the fluctuations is again divergent and we regularize with the same cut-off \( \Lambda \) on \( K \). Substituting the perturbative solutions \( (16) \), we find

\[ T_{\text{fluct}}^{tt}(t; \Lambda) = T_{N_{eq}}^{tt}(t; \Lambda) + T_{\delta N}^{tt}(t; \Lambda), \quad (28) \]

where the first term arises from the equilibrium distribution \( N_{eq} \) (eq. (17))

\[ T_{N_{eq}}^{tt}(t; \Lambda) \equiv \frac{T_0 \Lambda^3}{2\pi^2}, \quad (29) \]

while the second term (in frequency space) arises from \( \delta N_{L/T} \)

\[ T_{\delta N}^{tt}(\omega; \Lambda) \equiv \frac{h(\omega) T_0}{4\pi^2} \dot{C}_{\zeta 0} f(\omega, \dot{\gamma}_{\zeta 0}, \Lambda) \]

\[ + \frac{h(\omega) T_0}{\pi^2} \dot{C}_{\eta 0} f(\omega, 2 \dot{\gamma}_{\eta 0}, \Lambda). \quad (30) \]

As will be described in the next section, the divergences in \( T_{\text{fluct}}^{tt} \) and \( T_{\text{fluct}}^{ij} \) are absorbed by renormalizing the background fields, e.g. \( p_0 \) and \( \zeta_0 \). This renormalization procedure requires a clearer understanding how these bare parameters are defined, and how they depend on the cut-off \( \Lambda \).

B. Temperature shift

The bare parameters \( e_0, p_0, T_0, \zeta_0, \ldots \) are determined by modes (such as particle-like excitations) with wavenumbers above the cut-off, \( k > \Lambda \), which are not explicitly propagated by the statistical hydrodynamic system. The goal of this section is to carefully explain how these parameters are defined and related to the physical equation of state \( (\epsilon(T), p(T)) \) from lattice QCD and the cut-off \( \Lambda \).

First consider the density matrix for non-hydrodynamic modes with wavenumbers above the cut-off \( k > \Lambda \). When the system is driven slightly out of equilibrium by the periodic compression and expansion, the density matrix for these modes \( \rho(\Lambda) \) can be decomposed as an equilibrium density matrix \( \rho_{eq}(T_0; \Lambda) \) and a non-equilibrium correction which is well characterized by a single gradient \( \delta \rho_{neq}(\Lambda) \propto \nabla \cdot u \)

\[ \rho(\Lambda) = \rho_{eq}(T_0; \Lambda) + \delta \rho_{neq}(\Lambda). \quad (31) \]

The temperature parameter \( T_0 \) (which will depend on time and \( \Lambda \)) is chosen so that the average energy density
above the cut-off \( e_0(t, \Lambda) \equiv \langle T^{ii}(t) \rangle_{k>\Lambda} \) equals the energy from the equilibrium density matrix \( \rho_{eq}(T_0; \Lambda) \) alone

\[
e_0(t, \Lambda) \equiv \langle T^{ii}(t) \rangle_{k>\Lambda} = e_{eq,0}(T_0(t; \Lambda); \Lambda), \tag{32}\]

i.e. \( T_0(t; \Lambda) \) is adjusted so that the energy moment associated with \( \delta \rho_{eq}(\Lambda) \) is zero \( \delta e_{eq}(t; \Lambda) = 0 \). (Otherwise the rhs of eq. (32) would have a correction proportional to \( \nabla \cdot u \).) Because of the constraint in eq. (32) we can drop the “eq” label below, i.e.

\[
e_0(t, \Lambda) = e_{eq,0}(T_0(t; \Lambda); \Lambda) = e_0(T_0(t; \Lambda); \Lambda). \tag{33}\]

In kinetic theory a similar constraint is imposed by requiring that the viscous correction to the distribution function \( \delta f_{\text{bulk}}(p) \) does not change the energy in the system \([18, 22]\). Once this prescription for \( T_0(t; \Lambda) \) is adopted, the stress computed with the density matrix \( \rho(\Lambda) \) is given by\(^3\)

\[
\langle T^{ij} \rangle_{k>\Lambda} = (1 - h) p_0(T_0; \Lambda) \delta^{ij} - \zeta_0(T_0; \Lambda) \nabla \cdot u \delta^{ij}, \tag{34}\]

where the partial pressure \( p_0(T_0; \Lambda) \) from modes above \( \Lambda \) is determined by the equilibrium density matrix, \( \rho_{eq}(T_0; \Lambda) \), while the bulk term comes from the viscous correction, \( \zeta_{eq}(\Lambda) \). This is the parameterization of the stress tensor (for \( k > \Lambda \)) that was used in eq. (2). The spatial stress tensor determines the bulk viscous correction \( \zeta_0 \nabla \cdot u \) only after the parameter \( T_0(t; \Lambda) \) is defined according to the Landau constraint in eq. (32) \([18, 22]\).

Later in this section we will define a temperature \( T(t) \) by imposing the Landau constraint on the whole system (including the energy of hydrodynamic fluctuations below the cut-off), and this will lead to a difference between \( T_0(t; \Lambda) \) and the cut-off independent temperature \( T(t) \).

Now we will relate the partial energy density and pressure, \( e_0(T_0; \Lambda) \) and \( p_0(T_0; \Lambda) \), to the equilibrium energy density and pressure, \( e(T_0) \) and \( p(T_0) \), as measured by lattice QCD. Indeed, \( e_0 \) and \( p_0 \) are cut-off dependent quantities and are determined by an equilibrium density matrix \( \rho_{eq}(T_0; \Lambda) \) which excludes hydrodynamic fluctuations below the scale \( \Lambda \). The contribution of such equilibrium hydrodynamic fluctuations to the energy density and pressure are given by eq. (29) and eq. (24) respectively, and thus the physical energy density and pressure are:

\[
e(T_0) = e_0(T_0; \Lambda) + \frac{T_0 \Lambda^3}{2\pi^2}, \tag{35a}\]

\[
p(T_0) = p_0(T_0; \Lambda) + \left[ 1 + \frac{T_0}{2} \frac{d\zeta_0}{dT_0} \right] \frac{T_0 \Lambda^3}{6\pi^2}. \tag{35b}\]

At a practical level these equations serve to define the \( e_0 \) and \( p_0 \) parameters that should be used in a stochastic hydro-code with a given cut-off \( \Lambda \) and physical equation of state \( e(T_0), p(T_0) \).

As discussed above, the temperature \( T(t) \) for the complete system (background+fluctuations) is adjusted so that the energy density calculated from the lattice equation of state \( e(T(t)) \) matches the energy of the partially equilibrated system \( \langle T^{ii}(t) \rangle \)

\[
\langle T^{ii}(t) \rangle = e(T(t)). \tag{36}\]

After imposing this constraint, the time dependent stress \( \langle T^{ii}(t) \rangle \) of the driven system will deviate from its equilibrium expectation, \( 3 p(T(t)) (1 - h(t)) \), and these deviations are described (up to long-time tails) by the bulk viscosity. Combining eqs. (27a),(28),(29), and (35a), the energy of the background+fluctuations is

\[
e(T(t)) = e(T_0(t; \Lambda)) + T_{\delta N}^{ii}(t; \Lambda). \tag{37}\]

where \( T_{\delta N}^{ii}(t; \Lambda) \) was defined in eq. (30). Thus, the temperature for the whole system \( T(t) \) (which is independent of the cut-off) is related to the temperature parameter of the subsystem \( T_0(t; \Lambda) \) by a small shift \( \Delta T \)

\[
T_0(t; \Lambda) = T(t) + \Delta T(t; \Lambda), \tag{38}\]

so that eq. (37) is satisfied. The temperature shift is given in frequency space by

\[
- \frac{de}{dT} \Delta T(\omega; \Lambda) = \frac{h(\omega)T}{4\pi^2} \bar{C}_{\zeta_0 f}(\omega, \bar{\gamma}_{\zeta_0}, \Lambda) + \frac{h(\omega)T}{\pi^2} \bar{C}_{\eta f}(\omega, 2\bar{\gamma}_{\eta f}, \Lambda). \tag{39}\]

and clearly depends on the cut-off since the \( T_0(t; \Lambda) \) was defined with respect to a specific subsystem labelled by \( \Lambda \). The temperature shift in the time domain takes the form

\[
- \frac{de}{dT} \Delta T(t; \Lambda) = - \frac{TA}{6\pi^2} \left[ \bar{C}_{\zeta_0} + 4 \bar{C}_{\eta f} \right] \nabla \cdot u + \text{finite}, \tag{40}\]

where \( \nabla \cdot u = \frac{1}{2} \dot{h} \) for this example. The divergent piece of the temperature shift is universal, but the finite corrections are not. This is verified by explicit calculation of the temperature shift for the Bjorken background in Appendix A. From practical perspective, eqs. (38) and (40) define how \( T_0 \) must be chosen for a stochastic hydro-code (with a specified cut-off \( \Lambda \)) to reproduce the correct physical bulk viscosity for long wavelength hydrodynamic modes and a physical equation of state. This is detailed in the next section\(^4\).

\(^3\) In the current setup \( \nabla \cdot u = \frac{1}{2} \dot{h} \).

\(^4\) In defining \( T_0 \) from \( T \), \( \Lambda \), and \( \nabla \cdot u \), the finite remainder in eq. (40) can be chosen in any convenient way.
C. Renormalized background and long time tails

Once the temperature shift $\Delta T(t; \Lambda)$ is obtained, the remaining divergences in $T^\eta_{\text{fluct}}$ can be absorbed by pressure and bulk viscosity renormalization. Using eqs. (21a), (23), (24), and (35b), the statistically averaged spatial stress tensor trace reads

$$\langle T^{ii} \rangle(t) = 3 \left[ 1 - h(t) \right] p(T_0(t; \Lambda)) - \frac{9}{2} \dot{h}(t) \zeta_0 + T_{3N}^{ii}(t; \Lambda).$$

where $T_{3N}^{ii}$ is given in eq. (25).

Now we will shift the temperature parameter $T_0$ in the pressure to the physical temperature $T(t)$ determined by Landau matching (37), $p(T_0) = p(T) + p'(T)\Delta T$. The fluctuation contribution $T_{3N}^{ii}(t; \Lambda)$ and the temperature parameter $\Delta T(t; \Lambda)$ both diverge as $-i\omega h(\omega)\Lambda$. These two terms gracefully combine to produce a positive definite renormalization of bulk viscosity $\zeta_0$ in the term $-\frac{9}{2} \dot{h}(t) \zeta_0$.

$$\zeta(T) = \zeta_0(T; \Lambda) + \frac{T\Lambda}{18\pi^2} \left[ \frac{C_0^2}{\gamma_0^2} + 4 \frac{C_{\eta 0}^2}{2\gamma_0^2} \right].$$

In this step the coefficients in front of the linear divergences in $\Delta T$ and $T_{3N}^{ii}$ have neatly come together to complete the squares of $C_0^2$ and $C_{\eta 0}^2$ defined by eq. (19). Thus the renormalization of the bulk viscosity is positive and only necessary in a system with broken scale symmetry. We have confirmed that the bulk viscosity renormalization is universal by computing it for a Bjorken expanding background (see Appendix A).

Once all divergences are absorbed by renormalization, the stress tensor becomes finite and cut-off independent. In the presence of background expansion, there are remaining finite corrections from the fluctuations in $T_{3N}^{ii}$. The total stress tensor is

$$\langle T^{ii} \rangle(t) = 3 \left[ 1 - h(t) \right] p(T(t)) - \frac{9}{2} \dot{h}(t) \zeta(T(t))$$

$$- \int \frac{d\omega}{2\pi} e^{-i\omega t} h(\omega) |\omega|^{3/2} \sqrt{2} \left( 1 + i\sgn(\omega) \right)$$

$$\times \frac{\tilde{T}}{4\pi^2} \left[ \tilde{C}_0^2 \left( \frac{1}{\gamma_0} + 4 \tilde{C}_{\eta 0}^2 \left( \frac{1}{2\gamma_0^2} \right) \right)^{3/2} \right],$$

and has a term with $|\omega|^{3/2}$, which cannot be expressed by local time derivatives. This term is not analytic at $\omega = 0$ and derives from the out-of-equilibrium fluctuations in the kinetic regime $k \sim k_s$.

With $\langle T^{tt} \rangle$ and $\langle T^{ii} \rangle$ known, we can write down the hydrodynamic equations for statistically averaged hydrodynamics with noise

$$0 = \frac{d}{dt} \langle T^{tt} \rangle + \frac{3}{2} h \langle T^{ii} \rangle + \frac{1}{2} \dot{h} \langle T^{ii} \rangle.$$  

Since the non-analytic term in $\langle T^{ii} \rangle$ is of $\mathcal{O}(h)$, the rest frame energy density $\dot{e}(t)$ evolves according to

$$0 = \dot{e}(t) + \frac{3h}{2} \left[ e(t) + p(t) \right],$$

and we obtain the solution:

$$e(t) = \bar{e} - \frac{3h(t)}{2} (\bar{e} + \bar{p}),$$

which will be used to calculate the response function in the next section.

D. Response function in the bulk channel

The non-analytic behavior in $\omega$ is also present in the response function in the bulk channel. In the frequency space, the linear response of stress tensor to the external gravitational field $h(\omega)$ is given by

$$\langle T^{ii} \rangle(\omega) = G_{R,ij}^{ii}(\omega, k = 0) \frac{1}{2} \bar{h}(\omega).$$

The response function $G_{R,ij}^{ii}$ is defined by

$$G_{ij}^{ii}(t, x) = \frac{\delta}{\delta h(\omega)} \left[ 2 \langle T^{ii} \rangle(\omega) \right] \bigg|_{h=0}$$

$= -6 \left( \bar{p} + \frac{3}{2} \bar{h} (\bar{e} + \bar{p}) \right) + 9i\omega \zeta - \frac{1 + i\sgn(\omega)}{4\sqrt{2\pi}} |\omega|^{3/2} \tilde{T}$

$$\times \left[ \frac{C_{ij}^2}{\gamma_i^2} \left( \frac{1}{\gamma_j^2} + 4C_{ij}^2 \left( \frac{1}{2\gamma_i^2} \right)^{3/2} \right) \right],$$

and the spectral function as

$$\rho^{ii,jj}(\omega) = 2\text{Im} G_{R,ij}^{ii}(\omega)$$

$$= 18\omega \bar{\zeta} - \frac{\omega |\omega|^{1/2} \tilde{T}}{2\sqrt{2\pi}} \left[ C_{ij}^2 \left( \frac{1}{2\gamma_i^2} \right)^{3/2} + 4C_{ij}^2 \left( \frac{1}{2\gamma_i^2} \right)^{3/2} \right].$$

This spectral function is consistent with a previous diagrammatic computation of the symmetrized correlation function $C^{ii,jj}$ (see the Appendix of ref. [16]) using the fluctuation-dissipation relation:

$$\rho^{ii,jj}(\omega) = \frac{\omega}{T} C^{ii,jj}(\omega, k = 0),$$

$$C^{ii,jj}(t, x) = \frac{1}{2} \left\{ \left\{ T^{ii}(t, x), \tilde{T}^{jj}(0, 0) \right\}_\text{conn} \right\}.$$

5 The term $18\omega \bar{\zeta}$ in $\rho^{ii,jj}(\omega)$ corresponds to a correlation of thermal noise in the stress tensor, which is not explicitly written in the calculation of $C^{ii,jj}$ [16].
We also computed $G_{RJ}^{ij}(\omega)$ diagrammatically in Appendix B and found identical results to eqs. (48) and (42) up to a contact term.

IV. SUMMARY

In this paper we applied the kinetic theory of hydrodynamic fluctuations developed in ref. [15] to a relativistic non-conformal fluid. We calculated the contribution of out-of-equilibrium hydrodynamic fluctuations to the energy momentum tensor, which renormalize the background hydrodynamic fields and the bulk viscosity $\zeta$. The bulk viscosity renormalization is proportional to the scaling symmetry breaking in the equation of state and can be used to estimate the minimal bulk viscosity value in a hot QCD medium.

In the main body of the paper, we considered a non-conformal charge-neutral fluid, which is driven out of equilibrium by a weak isotropic expansion (or compression). Analogous calculations for a Bjorken expanding system is summarized in the appendix. The relaxation of hydrodynamic fluctuations to equilibrium becomes appreciable for wavelengths $k \lesssim k_\star \sim \omega / \sqrt{\eta \zeta}$, where $\omega$ is the frequency of the background expansion and $k_\star$ defines the hydrokinetic regime.

We derive the hydro-kinetic equations for the two-point correlation functions $N_{AA}(\tau, \bm{k})$, eq. (13), of energy $\delta e$ and momentum $\delta \vec{p}$ density fluctuations in the presence of the expansion. The non-linear fluctuations $N_{AA}(\tau, \bm{k})$ contribute to the statistically averaged energy-momentum tensor $\langle T^{\mu\nu} \rangle$. The divergent part of the fluctuation contributions is regulated by an ultraviolet cut-off $\Lambda$. The cut-off dependences of $T_{\text{fluct}}^{\mu\nu}$ is (partially) absorbed by a universal renormalization of the background energy density $e_0$, the pressure $p_0$ and the bulk viscosity $\zeta_0$ (the same terms are found for the far-from-equilibrium Bjorken expansion, see Appendix A):

\begin{equation}
\begin{aligned}
e(T) &= e_0(T; \Lambda) + \frac{T A^3}{2 \pi^2}, \\
p(T) &= p_0(T; \Lambda) + \left(1 + \frac{T}{2} \frac{d e_0}{d T} \right) \frac{T A^3}{6 \pi^2}, \\
\zeta(T) &= \zeta_0(T; \Lambda) + \frac{T A}{18 \pi^2} \left[ \frac{1 + 3 T \frac{d e_0}{d T} - 3 c_{s0}^2}{2} \frac{e_0 + p_0}{\zeta_0 + \frac{2}{3} \eta_0} \right] + 4 \left(1 - 3 c_{s0}^2\right)^2 \frac{e_0 + p_0}{2 \eta_0}. 
\end{aligned}
\end{equation}

The bare unrenormalized background quantities reflect the physical properties of the modes above the cut-off $\Lambda$. The hydrodynamic fluctuations below the cut-off are dynamical in the hydrodynamics with noise and make an evolving contribution to the energy momentum tensor. We find that the renormalization of the bulk viscosity is proportional to the non-conformality of the equation of state, e.g. $(1 - 3 c_{s0}^2)^2$, in agreement with other estimates [18–23]. Using the parametrization of the equation of state from the lattice QCD simulations, we find that the fluctuation induced bulk viscosity is modestly enhanced around the QCD pseudo-critical temperature $T_c \sim 150$ MeV, where deviations from the conformality are the largest (see Fig. 1) [26]. A diagrammatic derivation of similar bound for bulk viscosity for a non-relativistic cold Fermi gas was recently presented in ref. [25] and we performed the calculation for the relativistic non-conformal fluid in Appendix B confirming the bulk viscosity renormalization, eq. (51c).

In a non-conformal system, the contribution to the energy density from the hydrodynamic fluctuations $T_{\text{fluct}}^{\mu\nu}$ is not completely accounted for by the equilibrium energy density of hydrodynamic modes (the cubic term in eq. (51a)). The additional cut-off dependent contributions are proportional to the divergence of the flow velocity $\nabla \cdot \vec{u}$ and are removed by a universal shift in the background temperature $T_0 = T(\Lambda) + \Delta T(\Lambda)$, eq. (40). Once the cut-off dependence in $T_{\text{fluct}}^{\mu\nu}$ is completely absorbed, the remaining finite contribution has a fractional power in the gradient expansion ($\propto \omega^{3/2}$) and makes an essential difference from hydrodynamics without noise (see eq. (43)). In the symmetrized correlation function of the energy-momentum tensor $C^{ij;JJ}$, these terms become proportional to $\omega^{3/2}$ and in coordinate space only decay with a power law tail $\propto t^{-3/2}$, and therefore are called the

\begin{equation}
\begin{aligned}
\eta(T) &= \eta_0(T; \Lambda) + \frac{T A}{30 \pi^2} \left[ \frac{e_0 + p_0}{\zeta_0 + \frac{2}{3} \eta_0} + \frac{7(e_0 + p_0)}{2 \eta_0} \right]. 
\end{aligned}
\end{equation}

This is a generalization from the conformal case [15, 17].

\textbf{Footnotes:}

6 Deviation by a contact term is permitted due to different definitions of the two-point functions [25].
long-time tails. Comparing the spectral functions $\rho^{ij,j}$, we find that our computation using the hydro-kinetic theory is consistent with the previous diagrammatic calculations [16].

In this publication we extended our previous work on hydro-kinetic theory to non-conformal systems close to equilibrium and undergoing a Bjorken expansion. A natural next step is to consider more general background evolution and systems with the net baryon number. It would be particularly rewarding to extend the hydro-kinetic theory to critical fluctuations around the critical point, which is the focus of the beam energy scan program at RHIC.

Appendix A: Bjorken background

In this section we generalize the hydro-kinetic equations for Bjorken expansion [15] to a non-conformal fluid. In the case of a Bjorken expansion, the space-time metric of a comoving frame is given by

$$ds^2 = -d\tau^2 + dx^2 + dy^2 + \tau^2 dy^2,$$

(A1)

on which a background solution satisfies

$$\frac{dc_0}{d\tau} = -\frac{e_0 + p_0}{\tau} \left[ 1 - \frac{\gamma_0}{\tau} + \cdots \right],$$

(A2)

where on the right-hand side we first-order the hydrodynamic gradient expansion. The evolution of the fluctuations $\varepsilon = e_0 + \delta e$, $\vec{g} \equiv (e_0 + p_0)\vec{v}$ is concisely expressed by introducing the vielbein variables,

$$\vec{G} = (G_x, G_y, G_z) \equiv (g^x, g^y, \tau g^\eta),$$

$$\vec{K} = (K_x, K_y, K_z) \equiv (k_x, k_y, k_z/\tau),$$

$$\vec{\Xi} = (\Xi_x, \Xi_y, \Xi_z) \equiv (\xi^x, \xi^y, \xi^\eta),$$

(A3a)

(A3b)

(A3c)

with which we define $\phi_a \equiv (c_{ab}\delta e, \vec{G})$. The evolution equation for $\phi_a$ is of the same form with the weak metric perturbation eq. (10a):

$$-iL_{ab}\phi_b + D_{ab}\phi_b + \Xi_a + P_{ab}\phi_b,$$

$$\langle \Xi_a(\tau, k)\Xi_b(\tau', -k') \rangle = 2D_{ab} \frac{T_0(e_0 + p_0)}{\tau} \times (2\pi)^3 \delta(k - k') \delta(\tau - \tau'),$$

(A4a)

(A4b)

with $\mathcal{L}$ and $\mathcal{P}$ given by eqs. (10b) and (10c). The coupling to the background $\mathcal{P}$ takes a form specific to the Bjorken flow:

$$\mathcal{P} = \frac{1}{\tau} \left( 1 + c_0^2 \tau + \frac{T_2}{2} \frac{dc_0^2}{dT_0} \right).$$

(A5)

The four modes of the fluctuations $\phi_A \equiv \phi_a(e_0, p_0)$, $A = +, -, T_1, T_2$ are defined using $e_0$’s in eq. (12), the eigenvectors of $\mathcal{L}$. They are given in the polar coordinates by the following real orthonormal vectors:

$$\vec{K} \equiv (\sin \theta_K \cos \varphi_K, \sin \theta_K \sin \varphi_K, \cos \theta_K),$$

$$\vec{T}_1 \equiv (-\sin \varphi_K, \cos \varphi_K, 0),$$

$$\vec{T}_2 \equiv (\cos \theta_K \cos \varphi_K, \cos \theta_K \sin \varphi_K, -\sin \theta_K).$$

The evolution of the two-point functions (14) is given by

$$\frac{\partial}{\partial \tau} N_{\pm \pm} = -\gamma_0 K^2 \left[ N_{\pm \pm} - \frac{T_0(e_0 + p_0)}{\tau} \right]$$

$$- \frac{1}{\tau} \left[ 2 + c_0^2 \tau + \frac{T_2}{2} \frac{dc_0^2}{dT_0} + \cos^2 \theta_K \right] N_{\pm \pm},$$

(A7a)

$$\frac{\partial}{\partial \tau} N_{T_1 T_1} = -2\gamma_0 K^2 \left[ N_{T_1 T_1} - \frac{T_0(e_0 + p_0)}{\tau} \right]$$

$$- \frac{2}{\tau} N_{T_1 T_1},$$

(A7b)

$$\frac{\partial}{\partial \tau} N_{T_2 T_2} = -2\gamma_0 K^2 \left[ N_{T_2 T_2} - \frac{T_0(e_0 + p_0)}{\tau} \right]$$

$$- \frac{2}{\tau} \left[ 1 + \sin^2 \theta_K \right] N_{T_2 T_2}. $$

(A7c)

The only difference from a conformal case [15] is a term $\propto dc_0^2/dT_0$ in eq. (A7a). The solutions at large $K$ behave asymptotically as

$$\frac{N_{\pm \pm}}{T_0(e_0 + p_0)/\tau} = 1 + \frac{c_0^2 - \frac{T_2}{2} \frac{dc_0^2}{dT_0} - \cos^2 \theta_K}{\gamma_0 K^2 \tau} + \cdots,$$

(A8a)

$$\frac{N_{T_1 T_1}}{T_0(e_0 + p_0)/\tau} = 1 + \frac{c_0^2}{\gamma_0 K^2 \tau} + \cdots,$$

(A8b)

$$\frac{N_{T_2 T_2}}{T_0(e_0 + p_0)/\tau} = 1 + \frac{c_0^2 - \sin^2 \theta_K}{\gamma_0 K^2 \tau} + \cdots. $$

(A8c)

The total energy-momentum tensor is calculated from two contributions: the background part and the fluctuation part:

$$\langle T^{xx} \rangle = p_0 - \frac{1}{\tau} \left( \zeta_0 - \frac{2\eta_0}{3} \right) + T_{\text{fluct}}^{xx},$$

(A9a)

$$\langle T^{yy} \rangle = p_0 - \frac{1}{\tau} \left( \zeta_0 - \frac{2\eta_0}{3} \right) + T_{\text{fluct}}^{yy},$$

(A9b)

$$\langle T^{\eta\eta} \rangle = p_0 - \frac{1}{\tau} \left( \zeta_0 + \frac{4\eta_0}{3} \right) + \tau^2 T_{\text{fluct}}^{\eta\eta},$$

(A9c)

$$\langle T^{\tau\tau} \rangle = e_0 + T_{\text{fluct}}^{\tau\tau}.$$
with

\[ T^{\tau\tau}_{\text{fluct}} = \frac{\langle G^2 \rangle}{e_0 + p_0}, \]  
\[ T^{xx}_{\text{fluct}} = \frac{\langle (G_x)^2 \rangle + \frac{2}{\tau} \frac{d}{dt} \langle (c_{a0} \delta e)^2 \rangle}{e_0 + p_0}, \]  
\[ T^{yy}_{\text{fluct}} = \frac{\langle (G_y)^2 \rangle + \frac{2}{\tau} \frac{d}{dt} \langle (c_{a0} \delta e)^2 \rangle}{e_0 + p_0}, \]  
\[ \tau^2 T^{\eta\eta}_{\text{fluct}} = \frac{\langle (G_y)^2 \rangle + \frac{2}{\tau} \frac{d}{dt} \langle (c_{a0} \delta e)^2 \rangle}{e_0 + p_0}. \]  

(A10a)

(A10b)

(A10c)

(A10d)

The K-space integrals are ultraviolet divergent and they are regularized by a cut-off at \(|K| = \Lambda\). The result is

\[ T^{\tau\tau}_{\text{fluct}} = \frac{T_0 \Lambda^3}{2\pi^2} - \frac{T_0 \Lambda}{6\pi^2\tau} \left[ \left( 1 + \frac{3T_0 \frac{d}{dt} c_{a0}}{2} - 3c_{a0} \right) \frac{1}{\gamma_0} \right] + \mathcal{O}(\Lambda^0), \]  
\[ (A11a) \]

\[ T^{xx}_{\text{fluct}} = T^{yy}_{\text{fluct}} = \left( 1 + \frac{T_0 \frac{d}{dt} c_{a0}}{2} \right) \frac{T_0 \Lambda^3}{6\pi^2} \frac{2}{\frac{d}{dt} T_0} \frac{1}{\gamma_0} \left( 1 + \frac{3T_0 \frac{d}{dt} c_{a0}}{2} - 3c_{a0} \right) + \mathcal{O}(\Lambda^0), \]  
\[ (A11b) \]

\[ \tau^2 T^{\eta\eta}_{\text{fluct}} = \left( 1 + \frac{T_0 \frac{d}{dt} c_{a0}}{2} \right) \frac{T_0 \Lambda^3}{6\pi^2} \frac{2}{\frac{d}{dt} T_0} \frac{1}{\gamma_0} \left( 1 + \frac{3T_0 \frac{d}{dt} c_{a0}}{2} - 3c_{a0} \right) + \mathcal{O}(\Lambda^0). \]  
\[ (A11c) \]

Noting that \( \nabla \cdot u = 1/\tau \) for a Bjorken expansion, we see that this result agrees with eq. (40), confirming that the divergent piece of the temperature shift is universal.

With this temperature shift, the energy-momentum tensor is

\[ \langle T^{\tau\tau} \rangle = e_0(T; \Lambda) + \frac{T \Lambda^3}{2\pi^2}; \]  
\[ (A13a) \]

\[ \frac{1}{3} \left( T^{xx} + T^{yy} + \tau^2 T^{\eta\eta} \right) = p_0(T; \Lambda) + \left( 1 + \frac{T \frac{d}{dt} c_{a0}}{2} \right) \frac{T \Lambda^3}{6\pi^2} \frac{2}{\frac{d}{dt} T_0} \frac{1}{\gamma_0} \left( \frac{C_2^0}{\gamma_0} + 4 \frac{C_0^{20}}{2\gamma_0} \right) + \mathcal{O}(\Lambda^0), \]  
\[ (A13b) \]

\[ - \frac{\zeta_0(T; \Lambda)}{\tau} - \frac{T \Lambda}{18\pi^2\tau} \left[ \frac{C_2^0}{\gamma_0} + 4 \frac{C_0^{20}}{2\gamma_0} \right] + \mathcal{O}(\Lambda^0), \]  
\[ (A13c) \]

\[ \frac{1}{4} \left( T^{xx} + T^{yy} - 2T^{\eta\eta} \right) = \frac{\eta_0(T; \Lambda)}{\tau} + \frac{T \Lambda}{30\pi^2\tau} \left[ \frac{1}{\gamma_0} + \frac{7}{2\gamma_0} \right] + \mathcal{O}(\Lambda^0), \]  
\[ (A13d) \]

and energy density, pressure, and viscosities are renormalized as

\[ e(T) = e_0(T; \Lambda) + \frac{T \Lambda^3}{2\pi^2}; \]  
\[ (A14a) \]

\[ p(T) = p_0(T; \Lambda) + \left( 1 + \frac{T \frac{d}{dt} c_{a0}}{2} \right) \frac{T \Lambda^3}{6\pi^2}, \]  
\[ (A14b) \]

\[ \zeta(T) = \zeta_0(T; \Lambda) + \frac{T \Lambda}{18\pi^2} \left[ \frac{1}{\gamma_0} - \frac{7}{2\gamma_0} \right] + \mathcal{O}(\Lambda^0), \]  
\[ (A14c) \]

\[ \eta(T) = \eta_0(T; \Lambda) + \frac{T \Lambda}{30\pi^2} \left[ \frac{1}{\gamma_0} - \frac{7}{2\gamma_0} \right] + \mathcal{O}(\Lambda^0). \]  
\[ (A14d) \]

By comparing with the renormalization in a weak metric perturbation eq. (51), we can conclude that background field renormalization is also independent of background expansion.

**Appendix B: Long-time tails in diagrammatic approach**

In this section we re-derive the retarded Green function for the trace of energy momentum tensor, eq. (48), which was discussed in Sec. III D; using a diagrammatic one-loop calculation. This approach was pioneered in ref. [16] for the symmetric stress-stress correlations and applied to conformal and non-relativistic fluids respectively in ref. [17] and ref. [25].

First we find the symmetrized Green functions for hydrodynamic fields using the equations of motion coupled to thermal noise. For a static fluid, the linearized equations of motion can be Fourier transformed in frequency...
The retarded and symmetrized Green functions satisfies
space from eq. (7) to

\[ -i \omega \delta w + ic \partial_i k^i \delta v_i = 0, \]  \hspace{1cm} (B1a)

\[ -i \omega v^i + ic \partial_i k^i \delta w \]  

\[ + \gamma \eta k^2 (\delta_j^i - \hat{k}^j \hat{k}^i) v_j + \gamma \xi k^2 \hat{k}_i \hat{k}_j v^i + \Xi i = 0, \]  \hspace{1cm} (B1b)

\[ \left\langle \hat{\xi}_i (\omega, \mathbf{k}) \hat{\xi}_j (-\omega', -\mathbf{k}') \right\rangle = \frac{2T}{e + p} \frac{4\delta (\omega - \omega') \delta (\mathbf{k} - \mathbf{k}')} \]  

\[ \times [\gamma \eta k^2 (\delta_i j - \hat{k}_i \hat{k}_j) + \gamma \xi k^2 \hat{k}_i \hat{k}_j], \]  \hspace{1cm} (B1c)

where for simplicity we normalize perturbations and noise by enthalpy:

\[ \delta w (\omega, \mathbf{k}) = \frac{c_e \delta e (\omega, \mathbf{k})}{e + p}, \]  \hspace{1cm} (B2)

\[ v^i (\omega, \mathbf{k}) = \frac{g^i (\omega, \mathbf{k})}{e + p}, \]  \hspace{1cm} (B2)

\[ \hat{\xi}_i (\omega, \mathbf{k}) = \frac{\xi_i (\omega, \mathbf{k})}{e + p}. \]  \hspace{1cm} (B2)

The symmetrized correlation function, i.e. the symmetrized Green function, is then defined as

\[ G_{S}^{\delta w, \delta w} (\omega, \mathbf{k}) = \frac{1}{2} \sum_{\mathbf{k}', \mathbf{k}''} \frac{1}{2 \pi (2\pi)^3} \left\langle \delta w (\omega, \mathbf{k}) \delta w (-\omega', -\mathbf{k}') \right\rangle \]  \hspace{1cm} (B3)

Using the equations of motion for perturbations and the variance of noise, eqs. B1, one easily obtains the symmetrized correlator between different combinations of hydrodynamic fields:

\[ G_{S}^{\delta w, \delta w} (\omega, \mathbf{k}) = \frac{2T}{e + p} c^2 k^2 D_{S}^{\text{sound}}, \]  \hspace{1cm} (B4a)

\[ G_{S}^{\delta v, \delta v} (\omega, \mathbf{k}) = \frac{2T}{e + p} \omega^2 \left[ (\delta^{ij} - \mathbf{k}^i \mathbf{k}^j) D_{S}^{\text{shear}} + \mathbf{k}^i \mathbf{k}^j D_{S}^{\text{sound}} \right], \]  \hspace{1cm} (B4b)

\[ G_{S}^{\delta v, \delta w} (\omega, \mathbf{k}) = G_{S}^{\delta w, \delta v} (\omega, \mathbf{k}) = \frac{2T}{e + p} c_s k^i \omega D_{S}^{\text{sound}}, \]  \hspace{1cm} (B4c)

where common terms are given by

\[ D_{S}^{\text{shear}} = \frac{\gamma \eta k^2}{\omega^2 + (\gamma \eta k^2 \omega)^2}, \]  \hspace{1cm} (B5a)

\[ D_{S}^{\text{sound}} = \frac{\gamma \xi k^2}{(\omega^2 - c_s^2 k^2)^2 + (\gamma \xi k^2 \omega)^2}. \]  \hspace{1cm} (B5b)

The retarded and symmetrized Green functions satisfies the classical dissipation-fluctuation theorem [27]

\[ G_{S} (\omega, \mathbf{k}) = \frac{2T}{\omega} \text{Im} G_{R} (\omega, \mathbf{k}) \]  \hspace{1cm} (B6)

and we find the retarded Green functions by contour integration according to Kramers-Kronig relations [27]

\[ G_{R} (\omega, \mathbf{k}) = \int \frac{d \omega'}{2 \pi} \frac{2 \text{Im} G_{R} (\omega', \mathbf{k})}{\omega' - \omega - i \epsilon}. \]  \hspace{1cm} (B7)

The retarded Green functions for hydrodynamic fields \( \delta w \) and \( \delta v \) are

\[ G_{R}^{\delta w, \delta w} (\omega, \mathbf{k}) = -\frac{c^2 k^2}{e + p} D_{R}^{\text{sound}}, \]  \hspace{1cm} (B8a)

\[ G_{R}^{\delta v, \delta v} (\omega, \mathbf{k}) = \frac{1}{e + p} \left[ (\delta^{ij} - \mathbf{k}^i \mathbf{k}^j) D_{R}^{\text{shear}} (\gamma \eta k^2) + \mathbf{k}^i \mathbf{k}^j D_{R}^{\text{sound}} (-c^2 k^2 + i \gamma \xi k^2 \omega) \right], \]  \hspace{1cm} (B8b)

\[ G_{R}^{\delta v, \delta w} (\omega, \mathbf{k}) = G_{R}^{\delta w, \delta v} (\omega, \mathbf{k}) = -\frac{c^2 k^2 \omega}{e + p} D_{R}^{\text{sound}}, \]  \hspace{1cm} (B8c)

with

\[ D_{R}^{\text{shear}} = \frac{1}{-i \omega + \gamma \eta k^2}, \]  \hspace{1cm} (B9a)

\[ D_{R}^{\text{sound}} = \frac{1}{\omega^2 - c^2 k^2 + i \gamma \xi k^2 \omega}. \]  \hspace{1cm} (B9b)

Similarly to the procedure in ref. [16], we expand the energy momentum tensor to quadratic order in perturbations (but neglect the charge density fluctuations)

\[ \frac{c^2 T^{00}}{e + p} = \frac{c^2 e}{e + p} + c_s \delta w + c_s^2 \vec{v}^2, \]  \hspace{1cm} (B10a)

\[ \frac{T^{ij}}{e + p} = \delta^{ij} \left[ -\frac{p}{e + p} + c_s \delta w + \frac{1}{2} \frac{d c_s^2}{dT} (\delta w)^2 \right] + \frac{1}{2} \frac{d c_s^2}{dT} \]  

\[ + \frac{1}{2} \frac{d c_s^2}{dT} \]  

\[ + \frac{1}{2} \frac{d c_s^2}{dT} + \frac{S^{ij}}{e + p}, \]  \hspace{1cm} (B10b)

where \( S^{ij} \) denotes the thermal noise in eq. (2) 9. We compute correlation function for

\[ \tilde{T}^{ii} (\omega, \mathbf{k}) = \frac{1}{e + p} \left[ T^{ii} - 3c^2 T^{00} \right] \]  

\[ = 3 \left[ -\frac{p - c^2 e}{e + p} \right] + \frac{1}{2} \frac{d c_s^2}{dT} (\delta w)^2 \]  

\[ + (1 - 3c^2) \vec{v}^2 + \frac{S^{ii}}{e + p}, \]  \hspace{1cm} (B11)

where \( 3c^2 T^{00} \) term is subtracted to get rid of the sound peak singularity. Since \( T^{00} \) is a conserved density, the subtraction does not modify the correlation function of \( T^{ij} \) at \( k \to 0 \) so that hereafter we refer to \( T^{ij} \) as \( T^{ii} \).

Then the retarded Green functions for energy momentum tensor eq. (47) is

\[ G_{R}^{\delta u, T^{ij}} (\omega, \mathbf{k} = 0) = \frac{i \omega \zeta}{(e + p)^2} \frac{1}{3} \left[ \frac{1}{3} - c_s^2 \right] G_{R}^{\delta w, \delta v} (\omega, \mathbf{0}) \]  

\[ + \frac{1}{2} \frac{d c_s^2}{dT} \]  

\[ + \frac{1}{2} \frac{d c_s^2}{dT} \]  

\[ + 2 \left[ \frac{1}{2} \frac{d c_s^2}{dT} \right] G_{R}^{\delta w, \delta v} (\omega, \mathbf{0}). \]  \hspace{1cm} (B12)

---

8 In general the Kramers-Kronig relation holds only up to subtractions of the ultraviolet contribution from the spectral function. Therefore, strictly speaking, the real part of of the retarded Green function \( G_R \) cannot be fixed within hydrodynamic theory.

9 By taking averages over eq. (B10), we can easily find the renormalization of energy density and pressure eq. (51).
To evaluate eq. (B12), we need to express the Green function of composite fields

\[ G^{a_1 a', a_2 a'}_R (t, x) = i \theta(t) \left( \left[ a^{i_1 a'}(t, x), a^{k_1 a'}(0, 0) \right] \right), \]  

in terms of two point functions of individual fields

\[ G^{a_1 a', a_2 a'}_R (\omega, k) = \int \frac{d\omega}{2\pi} \int \frac{d^3 k}{(2\pi)^3} \left[ G^{a_1 a'}_S (\omega', k) G^{a_1 a'}_R (\omega - \omega', -k) + G^{a_1 a'}_S (\omega', k) G^{a_2 a'}_R (\omega - \omega', -k) + G^{a_1 a'}_R (\omega', k) G^{a_2 a'}_S (\omega - \omega', -k) + G^{a_1 a'}_R (\omega', k) G^{a_2 a'}_S (\omega - \omega', -k) \right]. \]  

(B13)

Note that by causality a retarded Green function \( G_R (\omega, k) \) can have poles only in the lower \( \omega \)-complex plane, so \( G_R (\omega - \omega', k) \) is analytic in the lower \( \omega' \)-complex plane. Therefore we will close the \( \omega' \) integral in the lower complex plane of \( \omega' \), where only poles from the symmetric Green functions contribute.

For the shear-shear term in eq. (B15a), the symmetric Green function part can be expanded into

\[ \omega^2 D_S^{\text{shear}} (\omega', k) = \frac{i/2}{\omega' + i\gamma_2 k^2} - \frac{i/2}{\omega' - i\gamma_2 k^2}, \]  

(B16)

where the second term does not contribute to the contour integral in the lower complex plane. Evaluating the residue at \( \omega' = -i\gamma_2 k^2 \) pole we get the shear-shear contribution

\[ \left[ G^{s_1 s', s_2}_R \right]^{\text{shear}} (\omega, 0) = \frac{8T}{(e + p)^2} \int \frac{d^3 k}{(2\pi)^3} \frac{2\gamma_2 k^2}{2 - i\omega + 2\gamma_2 k^2}. \]  

(B17)

Substituting appropriate symmetric and retarded Green functions to eq. (B14) and exploiting the reflection and translational symmetries \( k \leftrightarrow -k, \omega' \leftrightarrow \omega - \omega' \), we write down the integrals for the Green functions necessary for the computation of eq. (B12)\(^\text{10}\)

Note that by causality a retarded Green function \( G_R (\omega, k) \) can have poles only in the lower \( \omega \)-complex plane, so \( G_R (\omega - \omega', k) \) is analytic in the lower \( \omega' \)-complex plane. Therefore we will close the \( \omega' \) integral in the lower complex plane of \( \omega' \), where only poles from the symmetric Green functions contribute.

For the shear-shear term in eq. (B15a), the symmetric Green function part can be expanded into

\[ \omega^2 D_S^{\text{shear}} (\omega', k) = \frac{i/2}{\omega' + i\gamma_2 k^2} - \frac{i/2}{\omega' - i\gamma_2 k^2}, \]  

(B16)

where the second term does not contribute to the contour integral in the lower complex plane. Evaluating the residue at \( \omega' = -i\gamma_2 k^2 \) pole we get the shear-shear contribution

\[ \left[ G^{s_1 s', s_2}_R \right]^{\text{shear}} (\omega, 0) = \frac{8T}{(e + p)^2} \int \frac{d^3 k}{(2\pi)^3} \frac{2\gamma_2 k^2}{2 - i\omega + 2\gamma_2 k^2}. \]  

(B17)

and the UV regulated \( k < \Lambda \) integral can be straightforwardly expressed in a cubic divergent piece \( \Lambda^3 \) and \( f(\omega, 2\gamma_2, \Lambda) \) defined in eq. (26).

The symmetric sound propagator in \( G^{s_1 s', s_2}_R \) can be also written as a sum of two terms

\[ \omega^2 D_S^{\text{sound}} (\omega', k) = \frac{i\omega'}{\omega^2 - c_s^2 k^2 - i\gamma_c k^2 \omega'} - \frac{i\omega'}{\omega^2 - c_s^2 k^2 - i\gamma_c k^2 \omega'}, \]  

(B18)

where the second term vanish under contour integration. The remainder can be further expanded as

\[ \frac{i\omega'}{\omega^2 - c_s^2 k^2 + i\gamma_c k^2 \omega'} = \frac{i/2}{\omega_+ - \omega_-} \frac{\omega_+}{\omega_+ - \omega_-} - \frac{i/2}{\omega_- - \omega_-} \frac{\omega_-}{\omega_- - \omega_-}. \]  

(B19)

Here \( \omega_\pm \) are the positions of poles satisfying

\[ \omega_+ + \omega_- = -i\gamma_c k^2, \quad \omega_- \omega_+ = -c_s^2 k^2. \]  

(B20)

For the ease of computation, retarded function part in the sound-sound contribution in eq. (B15a) can be also expressed in terms of \( \omega_\pm \) as follows

\[ \frac{-c_s^2 k^2 + i\gamma_c k^2 (\omega - \omega')}{\omega_+ - \omega_-} D_R^{\text{sound}} (\omega - \omega', -k) \]  

(B21)

\[ = -\frac{\omega_+^2}{\omega_+ - \omega_-} - \frac{1}{\omega_+ - \omega_-} - \frac{\omega_-^2}{\omega_+ - \omega_-} - \frac{1}{\omega_+ - \omega_-}. \]
Evaluating the $\omega'$ residues at $\omega' = \omega_{\pm}$, we obtain for the sound-sound piece of eq. (B15a)

$$
\left[ G_{R,\bar{\pi}^2,\bar{\pi}^2} \right]_{\text{sound-sound}}(\omega, 0) = \frac{8T}{(e + p)^2} \int \frac{d^3k}{(2\pi)^3} \frac{1}{4} \frac{1}{\omega^+ - \omega^-} \frac{i\omega}{8 - i\omega + \gamma k^2} + O\left(\omega^2, (\gamma k^2)^2/c_s k^2\right).
$$

(B23)

In the kinetic approximation $c_s k \gg \gamma k^2, \omega$ this reduces to

$$
\left[ G_{R,\bar{\pi}^2,\bar{\pi}^2} \right]_{\text{sound-sound}}(\omega, 0) = \frac{8T}{(e + p)^2} \int \frac{d^3k}{(2\pi)^3} \frac{1}{4} \frac{1}{8 - i\omega + \gamma k^2} + O\left(\omega^2, (\gamma k^2)^2/c_s k^2\right).
$$

(B24a)

Calculations for eq. (B15b) and eq. (B15c) proceeds analogously. The result is

$$
G_{R,\bar{\pi}^2,\pi^2}^{\delta w^2, \delta w^2}(\omega, 0) = \frac{8T}{(e + p)^2} \int \frac{d^3k}{(2\pi)^3} \frac{1}{4} \frac{1}{8 - i\omega + \gamma k^2}.
$$

(B24b)

The final combined result for the retarded Green functions, eq. (B12), is

$$
G_{R,\bar{\pi}^2}^{T^1, T^1}(\omega, 0) = 9i\omega - \frac{T \Lambda^3}{2\pi^2} \left[ 2(1 - c_s^2)^2 + \frac{2}{3} \frac{3}{2} \frac{d^2 c_s^2}{dT^2} \right]^2
$$

$$
+ \frac{T}{2\pi^2} \left[ 4C_T^2 f(\omega, 2\gamma k, \Lambda) + C_C^2 f(\omega, \gamma, \Lambda) \right].
$$

(B25)

To assure that imaginary part of $G_{R,\bar{\pi}^2}^{T^1, T^1}$ is independent of the cutoff, the background bulk viscosity is renormalized as in eq. (51). The cubic divergence in the real part of $G_{R,\bar{\pi}^2}^{T^1, T^1}$ does not have a corresponding counter term, but it is also not physical. The ambiguity in the real part of the retarded propagators $G_{R}$ is due to the fact that in flat spacetime the retarded Green functions cannot be measured directly and only the imaginary part is determined through the symmetric correlation functions $G_{S}$.
