Calamitic liquid crystals (LCs) based on 5-phenyl-pyrimidine derivatives have been designed, synthesized and characterized. The 5-phenyl pyrimidine core was functionalized with chiral $(R, R)$-2,3-epoxyhexoxy chain on one side and either siloxane or perfluoro terminated chains on the opposite side. The one involving perfluorinated chain shows $\operatorname{Sm} A^{*}$ phase over a wide temperature range of $82{ }^{\circ} \mathrm{C}$, whereas the siloxane analogue exhibits both $\operatorname{Sm} A^{*}$ and $\operatorname{Sm} C^{*}$ phases over broad range of temperatures and a weak first order $\operatorname{Sm} A^{*}$ $\mathrm{SmC} C^{*}$ transition is observed. For the siloxane analogue, the reduction factor for the layer shrinkage $R$ (relative to its thickness at the $\operatorname{Sm} A^{*}-\mathrm{Sm} C^{*}$ transition temperature, $T_{\mathrm{AC}}$ ) is $\sim$ 0.373 and layer shrinkage is $1.7 \%$ both at a temperature of $13{ }^{\circ} \mathrm{C}$ below the $T_{\mathrm{AC}}$. This compound is considered to be having "de Vries smectic" characteristics with the de Vries coefficient, $C_{\mathrm{deVries}}$ of $\sim 0.86$ on the scale of zero (the maximum layer shrinkage) to 1 (zero layer shrinkage). A three-parameter mean-field model is introduced for the orientational distribution function (ODF) to reproduce the electro-optic properties. This model explains the experimental results and leads to the ODF which exhibits a cross-over from the sugar-loaf to diffuse-cone ODF some $3{ }^{\circ} \mathrm{C}$ below $\mathrm{T}_{\mathrm{AC}}$.

## I. INTRODUCTION

Chiral smectic liquid crystals (LCs) having mesophases close to the room temperature are extremely useful for the next generation of displays and electro-optical devices. The devices based on ferroelectric smectics with extremely fast switching time $(\mu \mathrm{s})$ compared to the currently used slowly switching nematics (ms) are very promising [1]. However to obtain the defect free alignment in an LC cell over a broad range of temperatures, a pre-requisite of zero or a small layer shrinkage for practical applications is required and the achievement of which is still an open challenge. In principle, one is able to align the material very well in the nematic or smectic $A$ phases. However on a phase transition from $\operatorname{Sm} A$ to $\operatorname{Sm} C$, a tilt emerges whereby the molecular long axis $\boldsymbol{n}$ tilts relative to the layer normal $\boldsymbol{z}$ by an angle, $\theta$, that varies with temperature (Fig. 1a). Consequently, the layer spacing $\left(d_{C}\right)$ in the SmC phase decreases by a factor of $\cos \theta$ provided liquid crystalline molecules are close enough to being considered as rigid rods. The layer shrinkage arising from the tilt together with surface anchoring of molecules leads to chevron structure/s formed in the cell. These structures with opposite fold directions create zigzag defects at the interface in between the two oppositely folded cheverons. The emergence of these defects are impediments to a successful commercialization of devices based on ferroelectric LCs [2-4]. The solution is therefore focussed on to developing chiral LCs with a minimal or zero layer-shrinkage at the $\operatorname{Sm} A^{*}$ $\mathrm{SmC} C^{*}$ transition temperature and within the temperature range of $\mathrm{Sm} C^{*}$ [4]. It is normally the case that where the layer shrinkage is much lower than the scaling factor, $\cos \theta$, then the smectic phases of such compounds are known as 'de Vries smectics' (Fig. 1b).

A dozen or so compounds have been identified to have de Vries characteristics to the varying degrees of perfection. According to the semi-qualitative studies carried out so far, the calamitic LCs that combine low orientational order parameter but large lamellar orderings are likely to exhibit better de Vries type characteristics [5-9]. Most of the de Vries smectics contain trisiloxane/carbosilane backbones and perfluorinated side chains on either ends of the core; these terminations strongly promote lamellar orderings [10]. In this case, the alkane chains were replaced by an epoxy group (a precursor in the synthesis of the difluoro material). In order to obtain a large $P_{S}$ in the $\mathrm{Sm} C^{*}$ phase, it is pertinent to prepare highly enantiomeric enriched chiral molecules to avoid the cancelation effects of the oppositely
handed enantiomers. In the literature, excellent protocols are given for preparing epoxides from allylic alcohols with large enantiomeric excesses [11]. However to our knowledge, materials with enantiomeric enriched 5-phenyl pyrimidine epoxides have not yet been reported to have de Vries like behavior [12] before. The epoxide group may induce large electrical polarization. A use of 5-phenyl pyrimidine though as an aromatic core is extensively used in the synthesis of compounds that exhibit de Vries-like characteristics in chiral and non-chiral mesogens [13-15]. With this concept in mind, two new chiral materials containing epoxides in their structures have been designed, synthesized and investigated.

FIG. 1 Schematic representation of the molecular arrangements in the $\operatorname{Sm} A$ and $\operatorname{SmC}$ mesophases as per (a) conventional rigid-rod model and, (b) de Vries diffuse cone model [16]. $\boldsymbol{z}$ is the layer normal, $\boldsymbol{n}$ is the molecular long axis orientation, $\theta$ is the angle between $\boldsymbol{n}$ and $\boldsymbol{z}, d_{\mathrm{C}}$ and $d_{\mathrm{A}}$ are the layer spacing in $\operatorname{Sm} C$ and $\operatorname{Sm} A$, respectively.

In this article, we report synthesis and properties of the two 5-phenyl pyrimidine derivatives that contain the chiral $(R, R)$-2,3-epoxyhexoxy chain in conjunction with trisiloxane (adpc042) or perfluorinated (DR257) terminal chains (see appendix for the synthetic procedure). Both moieties are there0fore structurally related to each other, both use the same aromatic core and the epoxide chiral chain. In the DR257, siloxane group is replaced with perfluorinated butane as aliphatic linkage of six carbons with the aromatic core. A modification of the chain ending could have a significant effect on the properties and with the objective of finding its effect on the electro-optic properties, we decided to explore this further to establish a well-desired structure-property relationship. The mesophases formed by these compounds were characterized by differential scanning calorimetry (DSC), polarized
optical microscopy (POM), x-ray diffraction (XRD), electro-optics and dielectric spectroscopy. Characterization of the LCs shows that the perfluorinated epoxide DR257 exhibits a stable $\operatorname{Sm} A^{*}$ phase over a broad range of temperatures whereas the siloxane terminated analogue adpc042 exhibits both $\operatorname{Sm} A^{*}$ and $\operatorname{SmC} C^{*}$ phases. In this trisiloxane compound we achieve a layer shrinkage of $1.7 \%$, at a temperature of $-13{ }^{\circ} \mathrm{C}$ below the $\operatorname{Sm} A^{*}$ - $\operatorname{SmC} C^{*}$ transition temperature. Since adpc042 LC exhibits both $\operatorname{Sm} A^{*}$ and $\operatorname{SmC}$ * phases, properties of this compound are detailed below.

## II. EXPERIMENT

The phase sequence and the transition temperatures were found by DSC thermograms (Perkin-Elmer DSC-7 calorimeter). The experiment was carried out under cooling at a rate of $10{ }^{\circ} \mathrm{C} \mathrm{min}^{-1}$. The electro-optical studies of the two LCs were conducted using planar-aligned cells with parallel rubbed polyimide alignment layer KSRP-XX/D611P6NSS05. These cells were purchased from EHC, Japan. LC cells were studied by POM and electro-optics . Olympus BX 52, equipped with a rotating table was used. The hot-stage was fixed on to the rotating table. The hot stage was connected to a temperature controller, Eurotherm 2604. XRD measurements were carried out on Bruker D 8 diffractometer using $\mathrm{Cu}-\mathrm{K}_{\alpha}$ source with a wavelength 0.154 nm . Dielectric spectroscopic studies were performed using an Alpha High Resolution Dielectric Analyser (Novocontrol GmbH, Germany) in the frequency range 1 Hz 10 MHz . Indium Tin Oxide (ITO) coated glass substrates were used to make cells for studies of the real and imaginary parts of the dielectric permittivity. Substrates were coated with RN 1175 polymer (Nissan Chemicals, Japan) for obtaining the planar alignment. The cell thickness $(d)$ was controlled by Mylar spacers. UV-VIS spectrometer (Avaspec-2048) was used to measure $d$ through interference fringes. The ITO sheet resistance of the substrates (20 $\Omega / \square)$ is low enough to shift the peak frequency for the resistance of the ITO in series with the cell, beyond the experimental window of measurements. The dielectric spectra were analysed using Novocontrol WINDETA program.

## III. RESULTS AND DISCUSSIONS

## A. Differential Scanning Calorimetry and Polarizing Optical Microscopic Studies

The molecular structure and the transition temperatures of siloxane pyrimidine adpc042 and the fluorinated pyrimidine DR257 are given in Figs. 2 (a) and (b) (synthetic
procedures given in the appendix). Result of a DSC thermogram of DR257 is given in Fig. 2 c. Here two transitions with the enthalpies, $\Delta H$ of $\sim 17.2 \mathrm{Jg}^{-1}$ and $\sim 30.4 \mathrm{Jg}^{-1}$ at temperatures of $\sim 143{ }^{\circ} \mathrm{C}$ and $\sim 56{ }^{\circ} \mathrm{C}$ are recorded. To identify the mesophases, textures of a $9 \mu \mathrm{~m}$ planar cell filled with DR257 are recorded with POM. Images corresponding to the two mesophases are shown in the inset of Fig. 2c. On cooling from the isotropic temperature, the mesophase grows from the typical 'batonnet' structures to the focal conic texture. Both focal conic and dark homeotropic textures obtained by POM are the characteristics of $\operatorname{Sm} A^{*}$ phase [17]. Textures confirm that the phase transition from $\operatorname{Sm} A^{*}$ to a crystalline state is at a temperature of $56^{\circ} \mathrm{C}$.

(d)

FIG. 2 Molecular structures and the DSC thermograms of adpc042 [(a) and (d)] and DR257 [(b) and (c)] are given. The phase transition temperatures are obtained under the cooling cycle with a quasi-equilibrium condition at the rate of $\sim 1^{\circ} \mathrm{C} \mathrm{min}^{-1}$ using POM. The cooling curves of the DSC thermograms are obtained at the rate of $10^{\circ} \mathrm{C} \mathrm{min}^{-1}$. Iso $=$ isotropic phase, $\mathrm{Cr}=$ crystalline state. Insets in these two figures are the POM images of the mesophases seen under the crossed polarizers. Textures are recorded for a $9 \mu \mathrm{~m}$ planar-aligned cells in the cooling run.

A representative the DSC plot of adpc 042 LC under cooling exhibits two peaks (Fig. 2d). Both DR257 and adpc042 show the first order Iso -Sm $A^{*}$ transition with $\Delta H$ of $\sim 11.71$ $\mathrm{Jg}^{-1}$ and $17.2 \mathrm{Jg}^{-1}$ at a temperature of $\sim 82^{\circ} \mathrm{C}$ and $\sim 145^{\circ} \mathrm{C}$. This is confirmed by POM where the focal conic fan shaped texture from a $9 \mu \mathrm{~m}$ planar-aligned cell (Fig. 2d inset) is recorded. On lowering the temperature, the sample undergoes a weakly first order $\operatorname{Sm} A^{*}-\operatorname{SmC} C^{*}$ transition with $\Delta H$ of $\sim 0.49 \mathrm{Jg}^{-1}\left(0.069 \mathrm{kcal} \mathrm{mol}^{-1}\right)$ at $58{ }^{\circ} \mathrm{C}[12,18]$. For a conventional $\operatorname{Sm} A^{*}-\operatorname{SmC} C^{*}$ transition where the tilt angle stays at almost zero value in the $\operatorname{Sm} A^{*}$ phase down to the transition temperature $T_{\mathrm{AC}}$, the DSC thermogram exhibits a second order transition with a step in the baseline without a peak for the enthalpy of transition [19]. The $\mathrm{SmC} C^{*}$ phase of adpc042 is distinguishable from $\operatorname{Sm} A^{*}$ by POM where a fan shaped texture from a planar cell is altered to a broken fan shaped one (inset Fig. 2d). The dark homeotropic texture is changed to Schlieren texture on transition from $\operatorname{Sm} A^{*}$ to $\operatorname{Sm} C^{*}$. The entire replacement of trisiloxane in adpc 042 by tetra fluorocarbon chain in DR257, radically alters the mesomorphic behaviour, the temperature range of $\mathrm{Sm} A^{*}$ is increased from $23{ }^{\circ} \mathrm{C}$ to $89^{\circ} \mathrm{C}$, whereas $\mathrm{SmC}^{*}$ disappears. An increased temperature range of the $\mathrm{Sm} A^{*}$ phase in DR257 could be due to a large dipole moment associated with the fluorinated tail [20]. The siloxane groups in adpc042 enhance the thermal stability of the compound as well as lower the phase transition temperatures. These features may be of great importance from a point of view of the molecular design and applications.

The POM images of a planar-aligned cell of thickness $9 \mu \mathrm{~m}$ filled with adpc042 recorded at $63{ }^{\circ} \mathrm{C}\left(\sim 19{ }^{\circ} \mathrm{C}\right.$ below the Iso- $\mathrm{Sm} A^{*}$ transition temperature and $5{ }^{\circ} \mathrm{C}$ above the $T_{\mathrm{AC}}$ ), are given in Fig. 3. The rubbing direction $\boldsymbol{R}_{\boldsymbol{d}}$ is fixed at an angle, $\alpha=\sim 15^{\circ}$ to the polarizer $\mathbf{P}$.

FIG. 3 POM images of $\operatorname{Sm} A^{*}$ phase at a temperature of $63^{\circ} \mathrm{C}$ in a $9 \mu \mathrm{~m}$ planar-aligned cell filled with adpc 042 LC : (a) 0 V and (b) $5 \mathrm{~V}_{\mathrm{m}}{ }^{-1}$ (square wave AC electric field of 110 Hz ).

The electric field treatment of the LC cell gives rise to a uniform mono-domain texture (Fig. 3). An application of the external electric field across a cell in well-aligned $\operatorname{Sm} A^{*}$ phase produces a change in the color of the texture (compare Figs. 3a and 3b), due to an increase in the birefringence $\Delta n$ with the field, a characteristic of the de Vries behavior. In this phase, the molecules are tilted but are azimuthally disordered. The electric field produces a bias in the azimuthal distribution and the molecules tilt in a particular direction determined by the polarity of the field. The resulting $\operatorname{Sm} A^{*}$ is reduced to the same symmetry as $\operatorname{Sm} C^{*}$ phase through azimuthal ordering of the already tilted liquid crystalline molecules.

## B. X-ray diffraction(XRD)

Figure 4(a) shows the temperature dependence of the smectic layer spacing determined by the XRD experiment. On cooling the sample below the isotropic phase, the layer spacing in $\operatorname{Sm} A^{*}$ phase initially increases linearly with decreasing temperature. On approaching the $\operatorname{Sm} A^{*}-\mathrm{Sm} C^{*}$ transition temperature, the thickness reverses its trend within $\mathrm{SmA}^{*}$ from an increase to a decrease due to an emergence of the molecular tilt even in the SmA* phase. On further cooling of the sample cell, the layer thickness in the $\mathrm{SmC} C^{*}$ phase continues to decrease much more slowly than expected from a conventional smectic, in which the layer thickness scales as, $\cos \theta$. Figure 4 b shows the simulated molecular structures of the compound adpc042 using Hyperchem Program. The simulated length $l$, of the molecule is $\sim 31 \AA$. A possible molecular arrangement in layers is shown in Fig. 4b such that the total length of a pair of molecules is larger than the smectic layer thickness.

FIG. 4 (a) Temperature dependence of the smectic layer spacing determined by XRD ( $\mathbf{\Delta}$ ) relative to the layer thickness at the $\operatorname{Sm} A^{*}$ to $\mathrm{Sm} C^{*}$ transition temperature. The inset shows plots of the de Vries coefficient $C_{\text {deVries }}()$ and the reduction factor $R(\square) v s$. the
reduced temperature ( $T-T_{\mathrm{AC}}$ ). De Vries characteristics are defined in terms of $C_{\text {deVries }}$ and $R$. Measurements are carried out on a compound adpc042, (b) The simulated molecular structures of the compound adpc042.

A layer shrinkage of $1.7 \%$ is calculated from the XRD at a temperature of $13{ }^{\circ} \mathrm{C}$ below the $\operatorname{Sm} A^{*}-\mathrm{SmC} C^{*}$ transition temperature $T_{\mathrm{Ac}}$. The layer-shrinkage is small. The behaviour is similar to that in $\operatorname{Sm} A^{*}$ phase where the molecular directors in $\operatorname{Sm} A^{*}$ phase are distributed on to a cone where the azimuthal angle is degenerated. At the $\operatorname{Sm} A^{*}$ to $\operatorname{Sm} C^{*}$ transition, the tilt directions condense to within narrower limits, hence the disorder in the azimuthal angle disappears in the $\mathrm{SmC}^{*}$ phase. This process in itself requires no change in the layer thickness.

The reduction factor $R$ of a smectic LC is defined as,

$$
\begin{equation*}
R=\frac{\delta(T)}{\theta_{o p t}\left(T=T_{A C}\right)}=\frac{\cos ^{-1}\left(d_{C}(T) / d_{A C}\left(T=T_{A C}\right)\right)}{\theta_{o p t}\left(T=T_{A C}\right)} \tag{1}
\end{equation*}
$$

where $\delta(T)$ governs the layer thickness at a temperature $T$ within $\mathrm{SmC} C^{*}$ phase relative to the layer thickness at the $\operatorname{Sm} A^{*}-\operatorname{Sm} C^{*}$ transition temperature, $d_{\mathrm{AC}}$, on assuming that the rigid rod model is applicable to the LC under investigation [21]. $\theta_{\text {opt }}$ is the optical tilt angle determined by the POM (Fig. 5). According to Eq. (1), an ideal de Vries smectic with $d_{c}(T) \approx d_{A C}\left(T=T_{A C}\right.$ (Fig. 1b) produces a defect-free bookshelf geometry in $\mathrm{SmC} C^{*}$ phase with a reduction factor $R=0$, i.e. the short-range molecular tilt order at a lower temperature in the $\operatorname{Sm} A^{*}$ phase becomes long range close to the $\operatorname{Sm} A^{*}$ - $\operatorname{SmC} C^{*}$ transition temperature, where the maximum de Vries cone angle is equal to the saturated optical tilt angle at a temperature close to $T_{\mathrm{AC}}$. On entering the $\mathrm{Sm} C^{*}$ from $\operatorname{Sm} A^{*}$ phase, the azimuthal ordering of the molecular directors on the cone localizes these on to a single orientation. In this case, the layer contraction is absent and then $d_{\mathrm{C}} / d_{\mathrm{AC}} \approx 1$, and therefore $R \approx 0$. Li et al. suggested another method of characterizing de Vriesness from measurements of the layer thickness from XRD in terms of the de Vries co-efficient, $C_{\text {deVries }}$ [22]. The magnitude of this varies from ' 0 ' (classic rigid rod model with a maximum layer shrinkage) to 1 (ideal de Vries $\operatorname{Sm} A^{*}-\operatorname{SmC} C^{*}$ transition with zero layer shrinkage) such that

$$
\begin{equation*}
C_{\text {deVries }}=1-\left[\frac{\left(d_{A C}-d_{C}\right)}{\left(d_{A C}(1-\cos \theta)\right)}\right] \tag{2}
\end{equation*}
$$

The material adpc 042 gives rise to $R \approx 0.373$ at $13{ }^{\circ} \mathrm{C}$ below the $\mathrm{Sm} A^{*}-\mathrm{Sm} C^{*}$ transition temperature. Understandably, $R$ is away from zero but still low, hence the material is close to being a 'de Vries smectic'. An estimated value of $C_{\text {deVries }}$ is $\sim 0.86$ (Fig. 3 inset) at $13{ }^{\circ} \mathrm{C}$ below the $\operatorname{Sm} A^{*}-\operatorname{Sm} C^{*}$ transition temperature. The inset plot of Fig. 4 shows that both $R$ and $C_{\text {deVries }}$ are almost independent of temperature throughout the entire temperature range of the $\mathrm{SmC} C^{*}$ phase. The lowest reported value of $R$ so far is 0.17 for the chiral de Vries compound QL32-6 that exhibits a maximum layer contraction of only $0.2 \%$ at $3{ }^{\circ} \mathrm{C}$ below the SmA*-SmC* transitions with an optical tilt angle of $20^{\circ}$ [13].

## C. Electro-optical studies

The birefringence $\Delta n$ and the apparent optical tilt angle $\theta_{\text {Apparent }}$ are determined by recording the intensity of a transmitted beam of light through a LC cell by varying the positions of the polarizer and the analyzer. The procedure involves first keeping $\mathbf{P}$ fixed, and then rotating the analyzer automatically by various angles. This procedure is repeated for at least three different positions of the polarizer. From the data, $\Delta n$ and $\theta_{\text {Apparent }}$ are calculated. This procedure is different from that given by Park et al. [23], who record the transmitted intensity by rotating the sample and also record the transmitted intensity for the P and A (i) parallel and (ii) crossed to each other. The experiment is conducted by applying a triangular signal of frequency 46 Hz and an amplitude of $12 \mathrm{~V}_{0 \text {-peak }} \mu \mathrm{m}^{-1}$. Frequency of the field is chosen so as to allow sufficient time for the electro-optic switching to occur but to prevent ionic-conductivity contributing to the switching current. An amplitude of the voltage applied to the LC sample adpc042 is large enough so as to make the tilt angle increase slowly with field and then eventually to saturate by the field while avoiding a risk of damage to the sample by the applied electric field.

Figure 5 shows results of the birefringence $(\Delta n)$ as a function of temperature with and without electric field applied across the cell. On cooling the sample in the absence of field from the isotropic to $\operatorname{Sm} A^{*}$ phase, the magnitude of $\Delta n$ first increases slightly, but then starts to decrease within $\operatorname{Sm} A^{*}$ phase. This decrease in $\Delta n$ with temperature is due to the de Vries tilt appearing in the $\operatorname{Sm} A^{*}$ phase and a distribution of the in-layer directors occurring on to the cone. On further cooling the sample in the absence of electric field, $\Delta n$ suddenly increases
at the $\operatorname{Sm} A^{*}-\operatorname{Sm} C^{*}$ phase transition temperature $T_{\mathrm{AC}}$ followed by slow increase with a decrease in temperature. An application of the electric field $\left(\boldsymbol{E}=12 \mathrm{~V} \mu^{-1}\right)$ gives rise to a continuous rise in $\Delta n$ in the entire temperature range of the $\operatorname{Sm} A^{*}$ and $\operatorname{SmC} C^{*}$ phases. This field induced increase in $\Delta n$ is consistent with a change in the interference colors observed by POM (Fig. 3). The behavior is typical of the diffuse-cone model of $\operatorname{Sm} A^{*}$ phase with a weak first order $\operatorname{Sm} A^{*}-\operatorname{SmC} C^{*}$ phase transition (Fig. 2b). In the conventional $\operatorname{Sm} A^{*}$ of a LC, one may expect a small increase in $\Delta n$ to occur at the phase transition from a uniaxial $\operatorname{Sm} A^{*}$ (with zero tilt angle at $T=T_{\mathrm{AC}}$ ) to a biaxial $\mathrm{SmC}^{*}$ phase.

For adpc 042 , the measured value of the spontaneous polarization $\boldsymbol{P}_{S}[24]$ is plotted as a function of the reduced temperature in Fig. 5(b). Measurements are carried out on a $5 \mu \mathrm{~m}$ planar cell under the application of a square wave, frequency 110 Hz and large enough amplitude of $12 \mathrm{~V} / \mu \mathrm{m}$. The field is such that the helical structure for temperatures within $\mathrm{SmC}^{*}$ is unwound. It is interesting to note that the field induced polarization is much higher than for conventional ferroelectric liquid crystals. $\boldsymbol{P}_{S}$ increases with a reduction in temperature below the $\operatorname{Sm} C^{*}-\operatorname{Sm} A^{*}$ transition. The liquid crystalline material under study yields $\boldsymbol{P}_{\boldsymbol{S}} \sim 82.5 \mathrm{nC} \mathrm{cm}^{-2}$ for $T=\left(T_{A C}-30\right)^{\circ} \mathrm{C}$.

(a)

(b)

FIG. 5. Results given here are for adpc042. (a) The temperature dependence of the apparent tilt angle ( $\theta_{\text {Apparent }}$ ) and the birefringence $\Delta n$ by applying a maximum field of ( $12 \mathrm{~V} \mathrm{~mm}^{-1}$, red open circles); $\Delta n$ in the absence of the electric field (green square). Blue triangles denote the apparent tilt angle $\theta_{\text {Apparent }}$ for a field of $12 \mathrm{~V} / \mu \mathrm{m}$. Measurements are carried out on a $3 \mu \mathrm{~m}$ planar-aligned cell filled with adpc042 LC. (b) Spontaneous polarization $P_{S}$ measured under the cooling process from the isotropic temperature plotted as a function of $\left(\mathrm{T}-\mathrm{T}_{\mathrm{AC}}\right)$. The measurements are carried out on a $5 \mu \mathrm{~m}$ planar cell by applying a square wave AC voltage of $12\left[V_{\text {peak-peak }} / \mu \mathrm{m}\right]$ at a frequency of 110 Hz .

The measured values of $\theta_{\text {Apparent }}$ as a function of the electric field for different temperatures in the $\operatorname{Sm} A^{*}$ phase are plotted in Fig. 6a. The co-ordinate system and the definition of the various angles are given in Fig. 6b. At a higher temperatures in the $\operatorname{Sm} A^{*}$ phase, the magnitude of $\theta_{\text {Apparent }}$ is low and it increases linearly with the applied field. For temperatures closer to the $T_{\mathrm{AC}}, \theta_{\text {Apparent }}$ becomes nonlinear and it continues to increase slowly up to an electric field of $12 \mathrm{~V}_{\mathrm{m}}{ }^{-1}$ and eventually the tilt angle tends to saturate with the electric field.

FIG. 6. (a) Variation of the field induced apparent optical tilt $\theta_{\text {Apparent }}$ (symbols) and the corresponding fitted values (solid lines) for selected temperatures. Measurements are carried out in a $3 \mu \mathrm{~m}$ planar cell filled with adpc 042 LC. (b) The schematic of the dynamics with the laboratory co-ordinate system (c) Temperature dependence of the model parameters $A$ and $p_{0}$ found from the experiments, (d) temperature dependencies of the measured apparent tilt angle $\theta_{\text {Apparent }}$ (open symbols), the cone angle $\theta_{0}$ (the line with symbols) apositions of the distribution function of the maxima (lines) for the various electric field strengths applied across a planar-aligned cell.

Several approaches exist in the literature for modeling the unusual electro-optic characteristics of the de Vries smectics [25-30]. The Langevin-Debye model, proposed by

Fukuda [25] in a different context, was used by Clark et al. [27] to explain the electro-optical properties of de Vries smectic LCs. This model assumes that for a fixed temperature and zero electric field, the molecular directors in the $\operatorname{Sm} A^{*}$ phase are tilted but azimuthally distributed on to a cone. In this model, the free energy is expressed as $U=-p E \cos \varphi$, where $p$ is the local dipole moment. However, this model does not correctly explain the dependence of the induced apparent tilt angle ( $\theta_{\text {Apparent }}$ for the electric field) for temperatures rather closer to the $\operatorname{Sm} A^{*}-\mathrm{Sm} C^{*}$ transition temperature $T_{\mathrm{AC}}$. In 2013, the Boulder group [28] modified this model where they added an additional term involving the square of the electric field in the expression for the free energy. This is expressed as $U=-p_{0} E \sin \theta \cos \varphi(1+\alpha E \cos \varphi)$. Here, $\alpha$ is the phenomenological scaling factor and $p_{0} \sin \theta$ is the dipole moment of the domain correlated in the molecular tilt created by the condensation of azimuthal angles $\varphi$. The first term $-p_{0} E \sin \theta \cos \varphi$ corresponds to the interaction of the dipole with the field. The second term $-\alpha p_{0} E^{2} \sin \theta \cos ^{2} \varphi$ includes the tilt susceptibility that increases with the square of the field $E$ and it leads to a sigmoidal response in both $\Delta n$ and $\theta_{\text {Apparent }}$ with $E$. In this model, the field induced $\theta_{\text {Apparent }}$ varies between the values inferred from the $\Delta n$ at zero field $\left(\theta_{\min }\right)$ to the maximum electric field $\left(\theta_{\max }\right)$. These limiting values of $\theta_{\min }$ and $\theta_{\max }$ themselves are temperature independent but the actual values within these limits nevertheless are temperature dependent. Therefore, we propose a somewhat different model. This involves three parameters for explaining the electro-optic response where the mean-field free energy is expressed as:

$$
\begin{equation*}
U=-p_{0} E \sin \theta \cos \varphi+A^{2} \sin ^{2}\left(\theta-\theta_{0}\right) \tag{3}
\end{equation*}
$$

Here the first term, $p_{0} E \sin \theta \cos \varphi=\boldsymbol{P} \cdot \boldsymbol{E}$, describes the usual dipole interaction energy with the field. $|\boldsymbol{P}|,\left[=\left(p_{0} \sin \theta\right)\right]$, is the magnitude of the dipole moment of a tilt correlated domain. This first term of Eq. (3) is linear in the external electric field $\boldsymbol{E}$. The second term in this equation defines the cone distribution with a cone aperture angle of $2 \theta_{0}$ and a distribution width proportional to $\sqrt{k_{B} T} / A$. Here $k_{B}$ is the Boltzmann constant, $T$ is the absolute temperature and $A$ is the phenomenological co-efficient for the zero field molecular distribution. Note that for the case, $\theta_{0}<\sqrt{k_{B} T} / A$, the model produces "sugar-loaf" ODF (Fig. $7(\mathrm{a})$ ), while a larger $\theta_{0}$ combined with a narrower distribution width correspond to the "volcano" or "diffuse-cone" distribution (Fig. 7(a)). Thus both scenarios discussed in [31] are reproduced with the same expression for the free energy. Figure 7 b illustrates the trend of $\left[\left(k_{B} T / A\right)^{1 / 2}-\theta_{0}\right]$, as a function of the reduced temperature $\left(T-T_{A C}\right)$ for adpc 042 . One can see
that at 2 to 3 degrees below the phase transition, this function crosses zero. This is a crossover between the sugar-loaf and the diffuse-cone ODFs.

FIG. 7. (a) 2D schematic representation of sugar-loaf (dash-dot lines in blue colour) and diffuse-cone (solid lines in red colour) ODFs. (b) $\left[\left(\mathrm{k}_{\mathrm{B}} \mathrm{T} / \mathrm{A}\right)^{1 / 2}-\theta_{0}\right]$ plotted as a function of the reduced temperature ( $\mathrm{T}-\mathrm{T}_{\mathrm{AC}}$ ). Measurements are carried out on a $3 \mu \mathrm{~m}$ planar cell filled with adpc 042 .

For the range of the electric fields used, we observe no inflection point in the field dependence of $\theta_{\text {Apparent }}$ i.e. no change in the slope of the derivative of the angle at the point. Therefore, we can achieve a good fit of the experimental data to the model without using terms of higher powers of $E$.

In order to simulate the behaviour of $\theta_{\text {Apparent, }}$, we use the mean-field approach combined with equations for the optical response [28]. An average $\langle Y\rangle$ over the orientational distribution can be written as $\langle Y\rangle=\int_{0}^{2 \pi} \int_{0}^{\pi / 2} Y(\theta, \varphi) f(\theta, \varphi) \sin \theta d \theta d \varphi$, where the mean field $\operatorname{ODF} f(\theta, \varphi)$ is expressed as:

$$
\begin{equation*}
f(\theta, \varphi)=\exp \left[-U / k_{B} T\right] / \int_{0}^{2 \pi} \int_{0}^{\pi / 2} \exp \left[-U / k_{B} T\right] \sin \theta d \theta d \varphi \tag{4}
\end{equation*}
$$

The apparent electro-optical tilt angle $\theta_{\text {Apparent }}$ is given by:

$$
\begin{equation*}
\tan 2 \theta_{\text {Apparent }}=\frac{\langle\sin 2 \theta \cos \varphi\rangle}{\left\langle\cos ^{2} \theta-\sin ^{2} \theta \cos ^{2} \varphi\right\rangle} \tag{5}
\end{equation*}
$$

On fitting the experimentally obtained voltage dependencies of $\theta_{\text {Apparent }}$ to the above model, we obtain values of $p_{0}, A$ and $\theta_{0}$ each as a function of temperature (Fig. 6c, and 6d). All the parameters tend to increase on approaching $T_{\mathrm{AC}}$ as the cell is cooled from the isotropic state to the $\operatorname{Sm} A^{*}$ phase. Such an increase is in agreement with the previous models [27, 28].

Onusing the dipole moment of the correlated domain as $p_{0} \approx 5000 \mathrm{D}$ at $0.5^{\circ} \mathrm{C}$ above the $\operatorname{SmC} C^{*}-\operatorname{Sm} A^{*}$ phase transition temperature, we can estimate the effective size of a domain using the procedure similar to that adopted by Shen et al. [28]. The effective molecular dipole moment can be estimated from the polarization density measurements performed on a planar-aligned cell in $\mathrm{SmC}^{*}$ phase. In this case $P_{S}$ is saturated at $69 \mathrm{nC} / \mathrm{cm}^{2}$; $\theta_{\text {Apparent }}=30^{\circ}$ at $\left(\mathrm{T}_{\mathrm{AC}}-19\right)^{\circ} \mathrm{C}$, with the molar mass, $M=590.3 \mathrm{~g} / \mathrm{mol}$, density $\rho=1.2$ $\mathrm{g} / \mathrm{cm}^{3}$, the dipole moment is found as $\mu_{\text {eff }}=\frac{P S M}{\rho N_{A} \sin \theta_{\text {Apparent }}} \approx 0.34 \mathrm{D}$. Therefore, the tiltcorrelated domain in our experiment contains approximately 6,000 to 15,000 molecules. The effective domain correlation length $\sqrt[3]{\frac{p_{0} \sin \theta_{\text {Apparent }}}{P_{S}}}$, at a temperature close to the $\operatorname{Sm} A^{*}$ $S m C^{*}$ phase transition, is of the order of 30 nm [30].

Parameter $A$ clearly favours the "volcano"- type distribution as illustrated by Fig. 8. A comparison of the cone angle $\theta_{0}$ that fits the experimentally obtained $\theta_{\text {Apparent }}$ for different fields is shown in Fig. 6d. Note that for higher field strengths, $\theta_{\text {Apparent }}$ exceeds $\theta_{0}$. This is indicative of a large electro-clinic effect. The solid lines in Fig. 6d show angular positions of the maximum in the ODF simulated for the two electric field strengths ( 5 and $12 \mathrm{~V}^{\prime} \mathrm{m}^{-1}$ ) here. The experimental values of $\theta_{\text {Apparent }}$ for $12 \mathrm{~V} \mu \mathrm{~m}^{-1}$ are slightly lower than for an angle for which $\theta_{\text {ODF }}$ is a maximum. This is expected from a highly distorted difuse-cone ODF, the distortion is brought about by the applied electric field.

Figures 8a-d show a 3D illustration of the ODF function obtained for a temperature of $\left(T_{\mathrm{AC}}+1\right)^{\circ} \mathrm{C}$. The ODF is normalized as given below such that its volume for different fields is a constant: $f_{3 D}=\frac{f(\theta, \varphi)}{\sqrt[3]{\int_{0}^{2 \pi} \int_{0}^{\pi / 2} f(\theta, \varphi)^{3} \sin \theta d \theta d \varphi}}$. Figure 8 c shows the cross-section of the ODF in the plane of the LC cell where the maximum of the ODF vs. apparent tilt angle is plotted. The electro-clinic effect for the following electric fields are given in Fig. 8: zero, moderate (1.3 $\mathrm{V} / \mu \mathrm{m}$ ) ("cone unwinding"), and for large fields; $12 \mathrm{~V} / \mu \mathrm{m}$ (tilt increases but $\varphi$ is condensed within a narrow range of values). Note that the modeled ODF shown in Fig. 8 corresponds to the core part of the mesogen that exhibits birefringence at visible wavelengths of light.

FIG. 8. The ODF of the smectic compound, adpc 042 , at a temperature of $T=\left(T_{\mathrm{AC}}\right.$ $+1)^{\circ} \mathrm{C}$ for different electric field strengths $\left(0 \mathrm{~V}, 1.3 \mathrm{~V} \mu \mathrm{~m}^{-1}\right.$, and $\left.12 \mathrm{~V} \mu \mathrm{~m}^{-1}\right)$. (a-c) are the axonometric projections of $f_{3 D}(\theta, \varphi)$.

To test different models, we fit experimental data of $\theta_{\text {Apparent }}$ as a function of the electric field at a temperature $1^{\circ} \mathrm{C}$ above the $\mathrm{Sm} A^{*}-\mathrm{Sm} C^{*}$ phase transition temperature, $\mathrm{T}_{\mathrm{AC}}$ (Fig. 9), to the following models: the fixed-angle hollow cone [27], the generalized mean-field model [28] and our 3-parameter mean-field model. For low fields data fitted to the various models is quite adequate. However for the medium and high electric fields, the 3-parameter model shows a closer fit to the experimental data. This is supported by drawing a comparison between sum of the squares of the residuals $\left(\chi^{2}\right)$ for the various fits as shown in the inset of Fig. 9. Though, the three models provide reasonable fit to the data, our proposed model has no intrinsic assumption of either the sugar-loaf or the diffuse cone type distribution, i.e. it is not limited to the assumption of a certain ODF in the SmA* phase. Therefore testing and discrimination among the models is carried out automatically during the fitting procedure. Moreover, the model produces a continuous function for the ODF, having a better physical significance.

FIG. 9. The experimental, $\theta_{\text {Apparent }}(\square)$ vs electric field E shown at a temperature of 1 ${ }^{\circ} \mathrm{C}$ above the $\mathrm{Sm} A^{*}-\mathrm{SmC} C^{*}$ phase transition temperature, $\mathrm{T}_{\mathrm{AC}}$, are fitted to various models: The hollow cone, the generalized mean Field (MF) and the 3 parameter MF one. A schematic representation of the ODFs for the corresponding three models is given in the inset.

The de Vries LCs normally exhibit large values of the electro-clinic coefficient (denoted by $e$ ) [19, 32, 33]. The electro-clinic response is recorded for the material adpc042 in a planar-aligned cell. The experiment is carried out by keeping the smectic layer normal at an angle of $22.5^{\circ}$ with respect to the polarizer. The light intensity $I$, transmitted through the LC cell, in the absence of the field $\boldsymbol{E}$ is given by:

$$
\begin{equation*}
I=I_{0} \sin ^{2}(2 \alpha) \sin ^{2}(\pi \Delta n d / \lambda) \tag{6}
\end{equation*}
$$

$I_{0}$ is the incident intensity, $\alpha$ is the angle between the molecular director and the polarizer, $\Delta n$ is the birefringence, $d$ is the cell thickness, and $\lambda$ is the wavelength of the incident light. When an electric field is applied across the cell, the transmitted intensity varies linearly with the induced tilt angle $\delta \alpha=\theta_{\text {ind }}$. Differentiating Eq. (6) with respect to $\alpha$ is given as:

$$
\begin{equation*}
\delta I=2 I_{0} \sin (4 \alpha) \sin ^{2}(\pi \Delta n d / \lambda) \theta_{\text {ind }} \tag{7}
\end{equation*}
$$

From Eqns. (6) and (7) and for $\alpha=22.5^{\circ}$ we obtain $\theta_{\text {ind }}=\delta I / 4 I$. Figure 10 shows $\theta_{\text {ind }}$ as a function of temperature over the temperature range of $\operatorname{Sm} A^{*}$ phase. The magnitude of $\theta_{\text {ind }}$
increases with decreasing temperature. On approaching, $T_{\mathrm{AC}}$, from the high temperature side of $\operatorname{Sm} A^{*}$, magnitude of $\theta_{\text {ind }}$ diverges and this corresponds to the divergence of the correlation length of the tilt domain and here the azimuthal angle is condensed to lie within narrower limits.

FIG. 10. The temperature dependence of electro-clinic response $\theta_{\text {ind }}$ of adpc042 (ㅁ): experimental value, red line (-): fitting to Eq. (7). The inset figure is the electroclinic co-efficient $e$ (red open circle ) calculated using the Eq. $e=\theta_{\text {ind }} / E$ as a function of temperature. Experiments were conducted under cooling within the temperature range of $\mathrm{Sm} A^{*}$ phase up to a temperature of $T=\left(T_{\mathrm{AC}}+1\right){ }^{\circ} \mathrm{C}$ by the application of $0.1 \mathrm{~V}_{0 \text {-peak }} \mu \mathrm{m}^{-1}$ (planar aligned cell, $d=5 \mu \mathrm{~m}$ sine wave AC voltage of 22 Hz ).

The amplitude of $\theta_{\text {ind }}$ with temperature can be expressed by the power law equation as follows [34]

$$
\begin{equation*}
\theta_{i n d}=\frac{C}{\left(T-T_{A C}\right)^{\gamma}} \tag{8}
\end{equation*}
$$

Here $C$ is the scaling constant, $T_{\mathrm{AC}}$ is the $\operatorname{Sm} A^{*}-\mathrm{Sm}^{*}$ transition temperature and $\gamma$ is the critical exponent. For the smectic material under investigation $\gamma=1.68$. For a conventional $\operatorname{Sm} A^{*}-\mathrm{Sm} C^{*}$ transition, $\gamma$ is 1.33 [35]. Values of $\gamma$ greater than 1.33 reflect the short-range correlation of molecular directors in three dimensions, again a characteristic of the de Vries smectics. The inset plot in Fig. 10 shows the temperature dependence of the electroclinic coefficient $e$, calculated from the definition of $e=\theta_{\text {ind }} / E$.

## D. Dielectric Spectroscopy

Figure 11a shows a three dimensional plot of temperature dependent dielectric loss $\operatorname{spectra}\left(\varepsilon^{\prime \prime}\right)$ of a planar aligned cell filled with the material adpc042 LC. Note that the temperature independent high frequency process is due to the resistance of ITO in series with the capacitance of the filled cell. The relaxation process in the $\operatorname{Sm} A^{*}$ phase corresponds to fluctuation of the tilt angle and this mode is known as the soft mode (SM). This arises mainly as the system approaches $T_{\mathrm{AC}}$ the elastic constant controlling the tilt fluctuations decreases or gets softer. The low frequency dielectric relaxations in the $\mathrm{Sm} C^{*}$ phase is associated with the Goldstone (GM) mode in which the molecular director is subjected to continual symmetry breaking.

FIG. 11. (a) A 3-D plot of temperature dependent dielectric loss spectra ( $\varepsilon$ ") of the compound adpc 042 (cell thickness, $d=10 \mu \mathrm{~m}$ ) in a planar-aligned cell. The dielectric measurements are carried out under cooling. Temperature stabilization is $0.05^{\circ} \mathrm{C}$ and the applied voltage is $0.1 \mathrm{~V}_{\mathrm{rms}}$ (b) Dielectric strength $\Delta \varepsilon$ (open blue squares $\square$ ) and the corresponding relaxation frequency $f_{R}$ (red open circles ) as a function of temperature. SM and GM refer to the soft and Goldstone modes, respectively.

The dielectric spectra are analysed using the Novocontrol WINFIT programme. The temperature dependent dielectric strength $\Delta \varepsilon$ and the relaxation frequency $f_{R}$ are obtained by fitting the dielectric spectra to the Havriliak-Negami Eq. [36]:

$$
\begin{equation*}
\varepsilon^{*}(\omega)=\varepsilon^{\prime}-i \varepsilon^{\prime \prime}=\varepsilon_{\infty}+\sum_{j=1}^{n} \frac{\Delta \varepsilon_{j}}{\left[1+\left(i \omega \tau_{j}\right)^{\alpha_{j}}\right]^{\beta_{j}}}-\frac{i \sigma_{d c}}{\varepsilon_{0} \omega} \tag{9}
\end{equation*}
$$

where, $\varepsilon_{\infty}$ is the high frequency permittivity depending on the electronic and atomic polarizability, $j$ is the number of relaxation processes which varies from 1 to $\mathrm{n}, \omega=2 \pi f$ is the angular frequency in radians, $\varepsilon_{0}$ is the free space permittivity, $\tau_{\mathrm{j}}$ is relaxation time of the $j^{\text {th }}$ process, $\Delta \varepsilon_{\mathrm{j}}$ is the dielectric strength and $\alpha_{\mathrm{j}}$ and $\beta_{\mathrm{j}}$ are the symmetric and asymmetric broadening parameters of the $j^{\text {th }}$ dielectric relaxation process related to the distribution of relaxation times. The term $\left(-i \sigma_{\mathrm{dc}} / \varepsilon_{0} \omega\right)$ gives the dielectric loss due to the ionic conduction at and is dominant at lower frequencies due to the inverse $\omega$ term. The relaxation frequency $f_{\mathrm{j}}$ of the $j^{\text {th }}$ process is related to $\tau_{\mathrm{j}}$ as [37]:

$$
\begin{equation*}
f_{j}=\frac{1}{2 \pi \tau_{j}}\left[\sin \left(\frac{\alpha_{j} \pi}{2+2 \beta_{j}}\right)\right]^{1 / \alpha_{j}}\left[\sin \left(\frac{\alpha_{j} \beta_{j} \pi}{2+2 \beta_{j}}\right)\right]^{-1 / \alpha_{j}} \tag{10}
\end{equation*}
$$

The temperature dependencies of $\Delta \varepsilon$ and $f_{R}$ are shown in Fig. 11b. The amplitude of $\Delta \varepsilon$ shows a pronounced increase when the system approaches $T_{\mathrm{AC}}$ from the $\operatorname{Sm} A^{*}$ phase. The maximum value of $\Delta \varepsilon$ at $T_{\mathrm{AC}}$ is 16.8 . The corresponding $f_{R}$ is decreasing in the $\operatorname{Sm} A^{*}$ phase with a sharper trend in its lower temperature range. Remarkably strong soft mode dielectric absorption is observed in the dielectric spectra of de Vries LCs in contrast to the compounds that exhibit a conventional $\operatorname{Sm} A^{*}$ [38-41].

## IV. CONCLUSION

We have designed and synthesised two 5-phenyl pyrimidine derivatives with siloxane and fluorocarbon chain terminations, both with a chiral $(R, R)$-2,3-epoxyhexoxy side chain. Mesophases formed by these compounds are investigated using a number of techniques: DSC, POM, XRD, electro-optical, and dielectric spectroscopy.

We find that the maximum layer contraction for the siloxane terminated adpc042 at a temperature of $13{ }^{\circ} \mathrm{C}$ below the $\operatorname{Sm} A^{*}-\mathrm{Sm} C^{*}$ transition is $1.7 \%$ and a reduction factor $R$ is 0.37 on a scale of 1 to 0 . This compound is considered to be a good "de Vries smectic" with the de Vries coefficient $C_{\text {deVries }}$ of 0.86 on the scale of 0 to 1 . The soft mode dielectric relaxation strength $\Delta \varepsilon$ shows a critical behaviour when the system approaches $\operatorname{Sm} A^{*}-\mathrm{SmC}^{*}$ transition from the high temperature side. The critical exponent of the electro-clinic response is found to be $\gamma=1.68$. Value of the exponent is much greater than 1.33 , found for most conventional smectics. Temperature dependence of the correlation length suggests that the material has de-Vries characteristics.

We introduce a three parameter MF model for describing the ODF of the molecular director in $\operatorname{Sm} A^{*}$ phase with a view of fitting the field-induced experimental apparent tilt angle $\theta_{\text {Apparent }}$ data as a function of the electric field. Close to the $\operatorname{Sm} A^{*}-\operatorname{Sm} C^{*}$ transition temperature, the birefringence in $\operatorname{Sm} A^{*}$ phase is seen to decrease with a reduction in temperature. This is due to the emergence of a non-zero value of cone angle $\theta_{0}$, the magnitude of which increases to $17^{\circ}$ as the $\mathrm{SmA}^{*}-\mathrm{SmC}^{*}$ phase transition is approached. The proposed model fits the experimental data on apparent tilt angle and leads to the diffuse-cone ODF, at temperatures close to the phase transition temperatures. However $\theta_{0}$ decreases with an increase in temperature and the ODF displays a cross over from the diffuse-cone to the sugar loaf at $\sim 3.5^{\circ} \mathrm{C}$ above $\mathrm{T}_{\mathrm{AC}}$.

Work was supported by 13/US/I2866 from the Science Foundation Ireland as part of the USIreland Research and Development Partnership program jointly administered with the United States National Science Foundation under grant number NSF-DMR-1410649. Financial support for the Belfast group was from the Department for Employment and Learning under with grant code USI 056. X-ray measurements were done in Warsawa, under the EU Cost ICI 1208 2014-17 project. We thank Professor Satyendra Kumar for co-ordinating the USIreland project.

## APPENDIX: SYNTHETIC PROCEDURE

All reagents were purchased from Sigma Aldrich, Fluorochem, Alfa Aesar, ABCR, Synthonix and used without any further purification. Solvents were purchased from Sigma Aldrich, DMF was purchased pre-dried, THF was dried using a sodium/benzophenone still under $\mathrm{N}_{2}$ and DCM was dried using $\mathrm{CaH}_{2}$. All reactions were generally carried out under argon using oven-dried glassware. TLC plates were performed on Merck silica gel $60 \mathrm{~F}_{254}$ and were visualized using a 254 nm light source. Flash column chromatography was performed on Fluorochem silica gel 60 (40-63 micron).
IR spectra were recorded using a Perkin Elmer Spectrum Two FT-IR spectrometer. ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ spectra were recorded at $25^{\circ} \mathrm{C}\left(\mathrm{CDCl}_{3}\right.$ as solvent and TMS as reference) using a Bruker 400 MHz Ultrashield (Avance 400). HRMS spectra were recorded using a Waters - TOF Electrospray micromass LCT premier. Optical rotations were recorded using a polarimeter Perkin Elmer: model 341 Polarimeter.

The synthesis of adpc042 was carried out through the scheme shown in FIG. 12.

FIG. 12. General scheme for the preparation of adpc042
Further details of synthesis and characterization of each stage of intermediates are given below:

The chemical structure of compound 1 is given in Fig. 13.

FIG. 13. Chemical structure of compound 1
5-Hexen-1-ol ( $0.62 \mathrm{~g}, 6.2 \mathrm{mmol}$ ) was dissolved in dry toluene $(15 \mathrm{~mL})$ and sealed in a schlenk under argon. Sodium ( $0.16 \mathrm{~g}, 7.00 \mathrm{mmol}$ ) was added as a solid and the solution was stirred at $50^{\circ} \mathrm{C}$ overnight. 5-Bromo-2-chloropyrimidine ( $1.00 \mathrm{~g}, 5.17 \mathrm{mmol}$ ) was added and the solution stirred for 8 hours at $50^{\circ} \mathrm{C}$. The solution was filtered, water $(20 \mathrm{~mL})$ was added and the crude extracted with ethyl acetate ( $3 \times 30 \mathrm{~mL}$ ). The product was purified by column chromatography (ethyl acetate: hexane, 1:9, $\left.\mathrm{R}_{\mathrm{f}}=0.45\right)$ to yield a colourless oil $(0.80 \mathrm{~g}, 3.11$ mmol, 60\%).
${ }^{\mathbf{1}} \mathbf{H} \mathbf{N M R}\left(\mathbf{4 0 0} \mathbf{~ M H z}, \mathbf{C D C l}_{\mathbf{3}}\right.$ ) $\boldsymbol{\delta}: 8.51(\mathrm{~s}, 2 \mathrm{H}), 5.81$ (ddt, $\left.J=6.67,6.67,10.18,16.91, \mathrm{H}\right), 4.98$ (m, 2H), $4.33(\mathrm{t}, J=6.60,2 \mathrm{H}), 2.12(\mathrm{~m}, 2 \mathrm{H}), 1.82(\mathrm{~m}, 2 \mathrm{H}), 1.57(\mathrm{~m}, 2 \mathrm{H})$.
${ }^{13} \mathbf{C}$ NMR (101 MHz, $\mathbf{C D C l}_{3}$ ) $\boldsymbol{\delta}: 164.15(\mathrm{C}), 159.75(2 \mathrm{CH}), 138.59(\mathrm{CH}), 115.01\left(\mathrm{CH}_{2}\right)$, $111.79(\mathrm{C}), 68.42\left(\mathrm{CH}_{2}\right), 33.55\left(\mathrm{CH}_{2}\right), 28.36\left(\mathrm{CH}_{2}\right), 25.36\left(\mathrm{CH}_{2}\right)$.
IR (film): $=3076,2936,1640,1570,1432,1332,1176,1122,1024,912,794 \mathrm{~cm}^{-1}$.

The chemical structure of the compound $\mathbf{2}$ in Fig. 10 is given in Fig. 14 and the synthesis and characterization are detailed below:

## FIG. 14. Chemical structure of compound 2

4-hydroxyphenylboronic acid $(0.32 \mathrm{~g}, 2.33 \mathrm{mmol})$ and $\mathbf{1}(0.50 \mathrm{~g}, 1.94 \mathrm{mmol})$ were sealed in a schlenk under argon. Toluene ( 12 mL ) was added and the solution degassed for 5 minutes. Degassed methanol ( 7 mL ) and potassium carbonate dissolved in degassed water ( 3 mL ) were added to the schlenk. Tetrakis(triphenylphosphine)palladium(0) ( $0.11 \mathrm{~g}, 0.10 \mathrm{mmol}$ ) was added as a solid and the solution was refluxed overnight. The crude was concentrated and water $(30 \mathrm{~mL})$ was added before extraction with DCM ( $3 \times 30 \mathrm{~mL}$ ). The organic phase was dried with magnesium sulphate and concentrated in vacuo. The product was purified by column chromatography (ethyl acetate: DCM, 15:85, where $\mathrm{R}_{\mathrm{f}}=0.57$ in ethyl acetate: hexane, $1: 1$ ) to yield a white solid ( $0.23 \mathrm{~g}, 0.85 \mathrm{mmol}, 44 \%$ ).

${ }^{13} \mathbf{C}$ NMR ( $\mathbf{1 0 1 ~ M H z}, \mathbf{C D C l}_{3}$ ) $\boldsymbol{\delta}: 164.22$ (C), 157.17 (C), $156.95(2 \mathrm{CH}), 138.61(\mathrm{CH}), 128.48$ (C), $127.98(2 \mathrm{CH}), 126.19(\mathrm{C}), 116.73(2 \mathrm{CH}), 114.97\left(\mathrm{CH}_{2}\right), 68.06\left(\mathrm{CH}_{2}\right), 33.55\left(\mathrm{CH}_{2}\right)$, $28.48\left(\mathrm{CH}_{2}\right), 25.38\left(\mathrm{CH}_{2}\right)$.
IR (film): $=3099,3022,2950,1602,1558,1434,1326,1270,1180,1072,924,834 \mathrm{~cm}^{-1}$.
HRMS (EI): The molecular weight for $\mathrm{C}_{16} \mathrm{H}_{19} \mathrm{~N}_{2} \mathrm{O}_{2}\left[\mathrm{M}+\mathrm{H}^{+}\right]$was calculated as 271.1447 and found to be 271.1446 .

The chemical structure of compound $\mathbf{3}$ is given in Fig. 15; synthesis and characterization are detailed below:

## FIG. 15. Chemical structure of compound 3

$2(0.22 \mathrm{~g}, 0.81 \mathrm{mmol})$ was dissolved in dry THF (12 mL) under argon. 1, 1, 1,3,3,5,5heptamethyltrisiloxane $(0.35 \mathrm{~g}, 1.59 \mathrm{mmol})$ and platinum(0)-1,3-divinyl-1,1,3,3tetramethyldisiloxane $(0.20 \mathrm{~mL}$ of 0.1 M solution, 0.02 mmol$)$ were added to the flask and the solution was stirred for 2 hours. The crude is concentrated and purified by column chromatography (ethyl acetate: hexane, $2: 8$, where $\mathrm{R}_{\mathrm{f}}=0.30$ in ethyl acetate: hexane, $3: 7$ ) to yield a colourless wax $(0.29 \mathrm{~g}, 0.59 \mathrm{mmol}, 73 \%)$.
${ }^{\mathbf{1}} \mathbf{H}$ NMR (400 MHz, $\mathbf{C D C l}_{\mathbf{3}}$ ) $\boldsymbol{\delta}: 8.65(\mathrm{~s}, 2 \mathrm{H}), 7.39(\mathrm{~d}, J=8.70), 6.96(\mathrm{~d}, J=8.72,2 \mathrm{H}), 5.37$ $(\mathrm{s}, 1 \mathrm{H}), 4.39(\mathrm{t}, J=6.72), 1.83(\mathrm{~m}, 2 \mathrm{H}), 1.42(\mathrm{~m}, 6 \mathrm{H}), 0.54(\mathrm{~m}, 2 \mathrm{H}), 0.08(\mathrm{~s}, 9 \mathrm{H}), 0.06(\mathrm{~s}$, 6 H,$), 0.02(\mathrm{~s}, 6 \mathrm{H})$.
${ }^{13} \mathbf{C}$ NMR (101 MHz, CDCl $_{3}$ ) $\boldsymbol{\delta}: 164.71$ (C), $157.08(\mathrm{CH}), 156.18(\mathrm{C}), 128.11(\mathrm{CH}), 128.08$ (C) $127.30(\mathrm{C}), 116.48(\mathrm{CH}), 68.19\left(\mathrm{CH}_{2}\right), 33.36\left(\mathrm{CH}_{2}\right), 29.07\left(\mathrm{CH}_{2}\right), 25.91\left(\mathrm{CH}_{2}\right), 23.39$ $\left(\mathrm{CH}_{2}\right), 18.47\left(\mathrm{CH}_{2}\right), 2.04\left(3 \mathrm{CH}_{3}\right), 1.50\left(2 \mathrm{CH}_{3}\right), 0.41\left(3 \mathrm{CH}_{3}\right)$.
IR (film): $=2958,1600,1442,1332,1258,1048,840 \mathrm{~cm}^{-1}$.
HRMS (EI): $\mathrm{m} / \mathrm{z}$ calcd for $\mathrm{C}_{23} \mathrm{H}_{41} \mathrm{~N}_{2} \mathrm{O}_{4} \mathrm{Si}_{3}\left[\mathrm{M}+\mathrm{H}^{+}\right]$493.2374, found: 493.2379.

The chemical structure of compound 4 is given in Figure 16 and other details are followed below:

FIG. 16. Chemical structure of compound 4
Trans-2-hexen-1-ol (1.00 g, 9.98 mmol$)$, Shi Epoxidation Diketal Catalyst ( $0.77 \mathrm{~g}, 3.00$ mmol ) and Tetrabutylammonium hydrogensulfate ( $0.06 \mathrm{~g}, 0.18 \mathrm{mmol}$ ) were dissolved in dimethoxymethane/acetonitrile $(100 \mathrm{~mL}, 2: 1)$. Acetic acid $(0.35 \mathrm{~mL})$ was added to potassium carbonate ( 70 mL of 0.1 M solution) and this was added to the reaction which was then cooled to $-10{ }^{\circ} \mathrm{C}$. Oxone $(8.48 \mathrm{~g}, 13.78 \mathrm{mmol})$ was dissolved in ethylenediaminetetraacetic acid disodium salt ( 50 mL of 0.004 M solution in water) and potassium carbonate $(8.00 \mathrm{~g}, 57.91$ mmol) was dissolved in water $(50 \mathrm{~mL})$. The oxone and the carbonate solution were added to the reaction flask dropwise over 3 hours while keeping the temperature below $0{ }^{\circ} \mathrm{C}$. Water was added and the organic phase extracted with DCM ( 3 x 50 mL ) before drying with magnesium sulphate and concentrating the solution. The epoxide was purified by column chromatography (hexane: diethyl ether, $2: 1->100 \%$ ether once product appears, $\mathrm{R}_{\mathrm{f}}=0.53$ in

DCM: ethyl acetate, $1: 1$ ) to yield a colourless oil ( $0.70 \mathrm{~g}, 5.99 \mathrm{mmol}, 60 \%$ ). The column was compacted using hexane: diethyl ether, $2: 1$ and $1 \%$ triethylamine to neutralize the silica.
${ }^{1} \mathbf{H}$ NMR (400 MHz, $\mathbf{C D C l}_{3}$ ) $\boldsymbol{\delta}: 3.91$ (ddd, $J=2.58,5.58,12.53,1 \mathrm{H}$ ), 3.63 (ddd, $J=4.30$, $7.29,12.52), 2.96(\mathrm{td}, J=2.36,5.50,5.65,1 \mathrm{H}), 2.92(\mathrm{~m}, 1 \mathrm{H}), 1.74(\mathrm{~m}), 1.50(\mathrm{~m}, 3 \mathrm{H}), 0.96(\mathrm{t}$, $J=7.26,3 \mathrm{H})$.

The synthesis of DR257 was carried out through the scheme shown in FIG. 18, further details of each stage are provided below.

4

FIG. 18. General scheme for the preparation of DR257
Synthesis and characterization of the intermediates are given below. Structure of the compound $\mathbf{5}$ is given in Fig. 19 and details follow below:

FIG. 19. The Chemical structure of compound 5
$\mathrm{Na}_{2} \mathrm{~S}_{2} \mathrm{O}_{4}(0.040 \mathrm{~g}, 0.230 \mathrm{mmol})$ and $\mathrm{Na}_{2} \mathrm{HPO}_{4}(0.039 \mathrm{~g}, 0.276 \mathrm{mmol})$ were added to a mixture of 1-iodoperfluorobutane ( $0.955 \mathrm{~g}, 2.76 \mathrm{mmol})$, the alkene $\mathbf{1}(0.590 \mathrm{~g}, 2.30 \mathrm{mmol})$ in $\mathrm{H}_{2} \mathrm{O} / \mathrm{CH}_{3} \mathrm{CN}(12 \mathrm{~mL} 1: 3)$ [42]. The mixture was stirred overnight at room temperature. $\mathrm{Et}_{2} \mathrm{O}$ and $\mathrm{H}_{2} \mathrm{O}$ were added to the mixture and the phases were separed. The organic phase was extracted with $\mathrm{Et}_{2} \mathrm{O}(2 \times 10 \mathrm{~mL})$ and the combined organic phase was dried with magnesium sulphate. The solvent was removed at reduce pressure to led a yellow oil. This iodinated intermediate was used without further purification. $\mathrm{Bu}_{3} \mathrm{SnH}(0.802 \mathrm{~g}, 2.76 \mathrm{mmol})$ and a catalytic amount of AIBN $(12 \mathrm{mg})$ were added to the oil. The reaction mixture was heated to
$110^{\circ} \mathrm{C}$ for 24 h . The solvent was removed and the crude of reaction was purified by column chromatography on silica gel (hexane:ethyl acetate $=9: 1$ ) to give $5(0.208 \mathrm{~g}, 19 \%$ yield).
${ }^{\mathbf{1}} \mathbf{H} \mathbf{N M R}\left(\mathbf{4 0 0} \mathbf{~ M H z}, \mathbf{C D C l}_{3}\right) \boldsymbol{\delta}: 8.51(\mathrm{~s}, 2 \mathrm{H}), 4.33(\mathrm{t}, J=6.5,2 \mathrm{H}), 2.17-1.95(\mathrm{~m}, 2 \mathrm{H}), 1.90$ $-1.75(\mathrm{~m}, 2 \mathrm{H}), 1.63(\mathrm{~m}, 2 \mathrm{H}), 1.55-1.39(\mathrm{~m}, 4 \mathrm{H})$.
${ }^{13} \mathbf{C}$ NMR ( $\mathbf{1 0 1 ~ M H z}, \mathbf{C D C l}_{3}$ ) $\boldsymbol{\delta}: 164.11(\mathrm{C}), 159.79(2 \mathrm{CH}), 111.89(\mathrm{C}), 68.32\left(\mathrm{CH}_{2}\right), 31.15$ $\left(\mathrm{CH}_{2}\right), 30.70\left(\mathrm{t}, J=22.3, \mathrm{CH}_{2}\right), 29.00\left(\mathrm{CH}_{2}\right), 28.69\left(\mathrm{CH}_{2}\right), 25.83\left(\mathrm{CH}_{2}\right), 20.29(\mathrm{t}, J=3.7$, $\mathrm{CH}_{2}$ ).
${ }^{19}$ F NMR ( $\mathbf{3 7 6} \mathbf{~ M H z}, \mathbf{C D C l}_{3}$ ) $\boldsymbol{\delta}:-81.07,-114.61,-124.51,-126.06$.
HRMS (EI): molecular weight calculated for $\mathrm{C}_{14} \mathrm{H}_{15} \mathrm{BrF}_{9} \mathrm{~N}_{2} \mathrm{O}\left[\mathrm{M}+\mathrm{H}^{+}\right] 477.0224 \mathrm{~g}$; found 4 s 477.0208 g .

The chemical structure of compound 6 is given in Fig. 20 and other details follow:

FIG. 20. Chemical structure of compound 6
4-hydroxyphenylboronic acid $(0.070 \mathrm{~g}, 0.501 \mathrm{mmol})$ and $5(0.220 \mathrm{~g}, 0.462 \mathrm{mmol})$ were sealed in a schlenk under argon. Toluene ( 12 mL ) was added and the solution degassed for 5 minutes. Degassed methanol ( 4 mL ) and potassium carbonate dissolved in degassed water ( 1 mL ) were added to the schlenk. Tetrakis(triphenylphosphine)palladium(0) ( $0.029 \mathrm{~g}, 0.025$ mmol ) was added as a solid and the solution was refluxed overnight. The crude was concentrated and water ( 10 mL ) was added before extraction with DCM ( $3 \times 10 \mathrm{~mL}$ ). The organic phase was dried with magnesium sulphate and concentrated in vacuo. The product was purified by column chromatography (ethyl acetate:hexane, $3: 7$, where $\mathrm{R}_{\mathrm{f}}=0.35$ in ethyl acetate: hexane, $3: 7$ ) to yield a white solid $(0.169 \mathrm{~g}, 0.345 \mathrm{mmol}, 75 \%)$.
${ }^{1} \mathbf{H} \mathbf{N M R}\left(400 \mathbf{M H z}, \mathbf{C D C l}_{3}\right) \boldsymbol{\delta}: 8.65(\mathrm{~s}, 2 \mathrm{H}), 7.39(\mathrm{~d}, J=8.6,2 \mathrm{H}), 6.96(\mathrm{~d}, J=8.5,2 \mathrm{H}), 5.58$ $(\mathrm{s}, 1 \mathrm{H}), 4.39(\mathrm{~m}, 2 \mathrm{H}), 2.07(\mathrm{~m}, 2 \mathrm{H}), 1.86(\mathrm{~m}, 2 \mathrm{H}), 1.65(\mathrm{~m}, 2 \mathrm{H}), 1.57-1.42(\mathrm{~m}, 4 \mathrm{H})$. ${ }^{13} \mathbf{C}$ NMR ( $\mathbf{1 0 1 ~ M H z}, \mathbf{C D C l}_{\mathbf{3}}$ ) $\boldsymbol{\delta}: 164.56$ (C), $157.09(2 \mathrm{CH}), 156.32$ (C), 128.25 (C), 128.09 $(2 \mathrm{CH}), 127.09(\mathrm{C}), 116.51(2 \mathrm{CH}), 67.79\left(\mathrm{CH}_{2}\right), 30.94\left(\mathrm{t}, J=22.3, \mathrm{CH}_{2}\right), 29.05\left(\mathrm{CH}_{2}\right), 28.86$ $\left(\mathrm{CH}_{2}\right), 25.90\left(\mathrm{CH}_{2}\right), 20.28\left(\mathrm{t}, \mathrm{J}=3.7, \mathrm{CH}_{2}\right)$.
${ }^{19}$ F NMR ( $\mathbf{3 7 6} \mathbf{~ M H z}, \mathbf{C D C l}_{3}$ ) $\boldsymbol{\delta}:-81.07,-114.62,-124.51,-126.06$.
HRMS (EI): The molecular weight for $\mathrm{C}_{20} \mathrm{H}_{20} \mathrm{~F}_{9} \mathrm{~N}_{2} \mathrm{O}_{2}\left[\mathrm{M}+\mathrm{H}^{+}\right]$calculated as 491.1381 g , but was found as 491.1389 g .
The chemical structure of compound DR257 is given in Fig. 21 and the other details follow:

FIG. 21. Chemical structure of compound DR257
$6(0.220 \mathrm{~g}, 0.449 \mathrm{mmol}), 4(0.048 \mathrm{~g}, 1.03 \mathrm{mmol})$ and triphenylphosphine $(0.129 \mathrm{~g}, 0.490$ mmol ) were dissolved in dry THF $(10 \mathrm{~mL})$ under argon. Diethyl azodicarboxylate ( 0.085 g , 0.490 mmol ) was dissolved in dry THF ( 4 mL ) under argon before being added dropwise to the reaction flask. The flask was stirred overnight and then concentrated. The product was purified by column chromatography (ethyl acetate: hexane, 1.5:9, where $\mathrm{R}_{\mathrm{f}}=0.60$ in ethyl acetate: hexane, $3: 7$ ) to yield a white powder ( $0.82 \mathrm{~g}, 0.140 \mathrm{mmol}, 34 \%)$.
