Based on density functional calculation using the LDA+U method, we predict that Osmium compounds such as $CaOs_2O_4$ and $SrOs_2O_4$ can be stabilized in the geometrically frustrated spinel crystal structure. They show ferromagnetic order in a reasonable range of on–site Coulomb correlation U and exotic electronic properties, in particular a large magnetoelectric coupling characteristic of Axion electrodynamics. Depending on U, other electronic phases including 3D Weyl semi–metal and Mott insulator are also shown to occur.

Recently, a theoretical work has played a key role in discovery of novel topological insulators (TI), where time reversal symmetry protects unusual surface states which could lead to electronic devices with new functionalities [1–3]. Unlike other fields of condensed matter physics, where most compounds are found haphazardly, here a number of new materials has been suggested based on band structure calculations [4–6], some of which have been confirmed experimentally [7, 8].

In addition to these unusual electronic properties, introducing magnetic order on the surface of TIs can gap the surface states leading to completely insulating behavior. Here, novel phenomena such as the half quantum Hall effect [9] and quantized magnetoelectric effect [10] appear. The latter is parameterized by the quantized value of the Axion electrodynamics parameter $\theta = \pi$, [10, 11]. When time reversal symmetry, as well as spatial symmetries like inversion are broken in the bulk, the θ parameter is no longer quantized[12, 13]. However, in most known materials, it is extremely small, e.g. $\theta = 10^{-3}$, 10^{-4} in Cr_2O_3 and $BiFeO_3$ respectively [13]. Thus, achieving large values of the θ parameter, even at the absence of quantization, is an important materials challenge. For sufficiently large $\theta > \pi/2$, it has been proposed that magnetic domain walls will be associated with conducting channels at the sample surface[14]. Recent experimental progress in introducing magnetism via dopants [15, 16] in Bi_2Se_3 has been reported, as well as tuning of chemical potential into a small gap at the surface states [16]. Ideally however, magnetic topological insulators would combine band topology with intrinsic magnetic order, leading to large surface energy gaps. Unfortunately, most of known/proposed TIs involve p-electron orbitals, whose Coulomb interaction is weak and cannot support magnetism. Elements with $3d$ and $4d$ electrons do have large electronic correlations, but only small spin–orbit coupling (SOC). While both strong Coulomb interaction and large SOC is found in $4f$ and $5f$ electron systems, they usually form narrow energy bands, thus making it also hard to realize TI state

of matter (see [17] for an exception).

Due to the interplay of strong SOC and moderate electronic correlations, very recently systems with $5d$ electrons have received a lot of research attention[18–23]. It has been suggested that pyrochlore iridates exhibit novel phases such, e.g., TI[21, 22], and topological semi–metal (TSM) [23] behavior. As in pyrochlores $A_2B_2O_7$, spinel compounds AB_2O_4 have their four B–sites forming a corner sharing tetrahedral network. Furthermore, it may be expected that $5d$ systems in the spinel structure will be more tunable by pressure, external fields or by doping as compared to the closely packed pyrochlore lattice. Previous studies suggested that electronic d^5 configuration can realize an insulating state in $5d$ compounds[19]. Based on valence arguments we therefore focus on spinel osmates AOs_2O_4 (A is alkali metal element such as Mg, Ca, Sr, Ba), and investigate their electronic structure and magnetic properties using theoretical density functional calculations. Our numerical results reveal that the spinel structure can at least be a metastable crystallographic state for $5d$ elements which is additionally supported by a very recent synthesis of an empty iridium spinel compound Ir_2O_4[24]. Most interestingly, we find that ferromagnetic configuration is the ground state of the candidate orders considered and the electronic properties are sensitive to the A–site. Depending on the strength of the Coulomb correlation, they show some exotic properties, and for the rangle of $U's$ relevant to Os element, we predict $CaOs_2O_4$ and $SrOs_2O_4$ behave as magnetic axion insulators with $\theta = \pi$. The quantized value is protected by the inversion symmetry of the lattice. However, since the surfaces break inversion, typically they are gapped allowing us to define θ. Unlike other proposals for generating large θ, which exploit proximity to a topological insulator state[16], here a generalized parity criterion[25, 26] allows us to obtain large θ even when no proximate TI state exits.

We perform our electronic structure calculations for the spinel Osmates based on local spin density approximation (LSDA) to density functional theory (DFT) with
FIG. 1: Fragment of spinel crystal structure AOs_2O_4 (only Os and O atoms are shown) with the Os-O-Os angle being optimized.

TABLE I: Theoretically determined lattice parameters of spinel osmates. Angle denotes the Os-O-Os bond angle; Os-O and Os-Os denote the nearest neighbor Os-O bond length, and Os-Os bond length, respectively.

	Angle	Os-Os	Os-O
$CaOs_2O_4$	98.5^0	3.07 $\mathring{A}$	2.04 $\mathring{A}$
$SrOs_2O_4$	94.6^0	3.12 $\mathring{A}$	2.05$\mathring{A}$
$BaOs_2O_4$	103.1^0	3.28 $\mathring{A}$	2.11$\mathring{A}$
$Y_2Ir_2O_4$	129.7^0	3.60 $\mathring{A}$	1.99$\mathring{A}$

the full–potential, all–electron, linear–muffin–tin–orbital (LMTO) method[27]. Despite the $5d$ orbitals are spatially extended, recent theoretical and experimental work has given the evidence on the importance of Coulomb interactions in $5d$ compounds[19]. We utilize LSDA+U scheme[28] which is adequate for searching magnetically ordered insulating ground states [29] by taking into account the effect of Coulomb repulsion, and vary parameter U between 0 and 1.5 eV. Very recently, using the same scheme, we successfully predicted pyrochlore iridates to have an all–in/all–out non–collinear magnetic ordering[23], and our predictions have been confirmed by subsequent theoretical[30] and experimental[31] publications. We use a $24\times24\times24$ k–mesh to perform Brillouin zone integration, and switch off symmetry operations in order to minimize possible numerical errors in studies of various (non–)collinear configurations. As the experimental lattice parameters are not available, we search for the stable crystal structures by locating the minimum in the calculated total energy as a function of the lattice constant and internal atomic coordinates.

Spinel structure (see Fig. 1) forms space group $Fd\bar{3}m$. In order to allow its relaxation, we change the lattice constant from 13 a.u. to 18 a.u. and vary the Os-O-Os bond angle from 90^0 to 120^0 with a step of 1^0. We confirm that the choice of Coulomb U has only small effect on the lattice, and list the lowest energy structures obtained by LDA+SO (U=0) calculations in Table I. The structural stability has further been checked by studying various energy surfaces, chemical stability with possible reactans, other crystal structures and by calculating the phonon spectrum. This is discussed in Supplementary Information. For comparison, in Table I we also list the same parameters for the pyrochlore iridate $Y_2Ir_2O_7$. We see that the A–site element has a considerable effect on the Os–O bond angle and its length. As we discuss below, this allows us to control the electronic structure in Osmates and design exotic topological phases.

Our calculation predicts $MgOs_2O_4$ to be always metallic. We therefore do not discuss this compound here and concentrate our study on $CaOs_2O_4$. Its band structure from non–magnetic LDA+SO calculation is found to be metallic and shown in Fig.2a. The energy bands around the Fermi level appear as $J_{eff}=1/2$ states similar to the ones found in Sr_2IrO_4[19], and also in $Y_2Ir_2O_7$[23], where a metal rather than the interesting topological insulator scenario of [21] was obtained due to a 2–4–2 sequence of degeneracies at the Γ point. As importance of electronic correlations for $5d$ orbitals has been recently emphasized [19] and estimates for the values of U have been recently obtained between 1.4 and 2.4 eV in layered Sr_2IrO_4/Ba_2IrO_4 [32], we perform LSDA+U+SO calculations. Although, the accurate value of U is not known for spinels, we generally expect screening to be larger in 3D systems than that of 2D systems like Sr_2IrO_4. Furthermore, the Os–Os bond length is shorter than that of $Y_2Ir_2O_7$, and one can expect that the U in $CaOs_2O_4$ is also smaller than in $Y_2Ir_2O_7$. We therefore believe that the U is in the range between 0.5 and 1.5 eV. As in the pyrochlore structure, the Os spinel sublattice is geometrically frustrated. Naively one may expect that the magnetic configuration of $CaOs_2O_4$ is also non–colinear as recently found in $Y_2Ir_2O_7$[23]. To search for possible magnetic ground states, we perform calculations by starting with a number of different colinear and noncolinear magnetic configurations including ferro– and antiferromagnetic (FM/AFM) collinear (010), (110), (111), as well as non–collinear all–in/all–out, 2–in/2–out, 3–in/1–out and some perpendicular configurations promoted by Dzyaloshinsky–Moriya interactions[33]. We find that when U is less than 1.3 eV, only the FM-(010)-configuration retains its initial input magnetization direction; in all other configurations the moments depart from their input orientation. We also consider a two-up, two-down state which is suggested by the strong coupling limit where Os–O bonds are nearly 90°. As shown in [34], this leads to a 'Kitaev type' ferromagnetic interaction for spin components perpendicular to the plane. Although this structure is found to be stable for $U < 0.8$eV, it is higher in energy than the ferromagnetic state as shown in Table II. Regardless of the value of U, the FM configuration with magnetization along (010) is found to be

TABLE II: The spin $\langle S \rangle$ and orbital $\langle O \rangle$ moment (in μ_B) as well as the total energy E_{tot} per unit cell (in meV) for several selected magnetic configurations of $CaOs_2O_4$ as calculated using LSDA+U+SO method with U=0.5 eV. (E_{tot} is defined relative to the ground state.) The IDM is a co-planar configuration predicted for one sign of Dzyaloshinski Morya interactions in Ref. [33]

Configuration:	(010)	all–in/out	2–in/2–out	2–up/2–dn	IDM
$\langle S \rangle$	0.59	0.30	0.40	0.25	0.35
$\langle O \rangle$	0.14	0.21	0.22	0.14	0.16
E_{tot}(meV)	0.00	290	280	518	351

the ground state, and the energy difference between this and other configurations is quite large. To find magnetically ordered solutions, here we restricted our search by the original unit cell. Although, identifying more complex (such as incommensurate) forms of order recently discussed in pyrochlore Osmites $Cd_2Os_2O_7$[35], or in layered $SrCr_2O_4$ and $CaCr_2O_4$[36] would require a full analysis of the momentum–dependent magnon spectrum, we have checked for possible nesting of paramagnetic Fermi surfaces in our proposed Os spinels but cannot detect any strong features. This can be an indication that the incommensurate order is unlikely.

By examining lattice parameters in Table I, we see that the main difference between pyrochlore iridates and spinel osmates is the Os–O–Os bond angle and the Os–Os bond length. Due to the extended nature of $5d$ orbitals, the $5d$–$2p$ hybridization is strong and important for the inter–atomic exchange interaction. In $Y_2Ir_2O_7$, the Ir–O–Ir bond angle is much larger than 90^0 and Ir–O–Ir antiferromagnetic (AFM) superexchange interaction is dominant. This results in a strong magnetic frustration and non–colinear ground state magnetic configuration[23]. In contrast to pyrochlores, the Os–O–Os angle in spinel osmates is close to 90^0, while Os $5d$ orbitals have stronger overlap, making a direct ferromagnetic exchange to be important for $CaOs_2O_4$.

For the values of U=0.5 and 1.5 eV, electronic band structures along high symmetry lines appear to be insulating as shown in Fig.2b and Fig.2c, respectively. To check a possibility of the gap closure and the metallic behavior away from the high symmetry lines of BZ, we perform the calculation with $100 \times 100 \times 100$ k-mesh. This very dense k-mesh confirms that both U=0.5 and 1.5 eV calculations show the band gaps of 0.01 and 0.08 eV respectively.

In order to examine whether the system becomes an Axion insulator, we recall that similar to the Fu and Kane criterion[5], which is designed for non–magnetic systems with inversion symmetry, one can still use the parity eigenvalues for the states at eight Time Reversal Invariant Momenta (TRIM) in order to classify the magnetic insulators with inversion symmetry and evaluate the magneto–electric coupling[25, 26]: $\theta = \pi M (\mathrm{mod}\, 2)$,

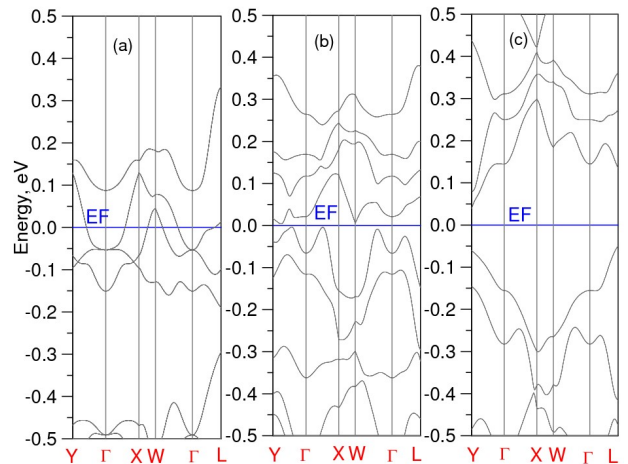

FIG. 2: Electronic band structure of $CaOs_2O_4$ shown along high symmetry direction. (a) LDA+SO; (b) LSDA+SO+U, with U=0.5 eV; (c) LSDA+SO+U, with U=1.5 eV

where $M = (\sum_k N_i)/2$, and N_i is the number of occupied states at the TRIM points i with odd parity. This allows us to analyze their topological electronic properties based on the parities of occupied bands. One must also verify the Chern number of the bands vanish, to define the magneto–electric coupling, which can be done by studying the evolution of the band structure from a trivial insulating state. The local environment of Os ion in spinels is oxygen octahedron, and the crystal–field splitting of Os $5d$ states is large, which makes the e_g band higher (about 2 eV) than the Fermi level. The bands close to the Fermi level are mainly contributed by t_{2g} mixed with O $2p$ orbitals. There are 4 Os per unit cell, thus the number of t_{2g} bands is 24. If all of 24 t_{2g} bands are fully occupied, the system cannot possess any topologically non–trivial properties. Noticing that Os occurs in its 3^+ valence, for an insulator to occur, there are 20 occupied and 4 empty t_{2g} bands. Thus, instead of analyzing 20 occupied bands, we alternatively look at the parities of 4 empty bands.

For the spinel lattice, the eight TRIM points are Γ, X, Y, Z, and four L points. For the Γ point, all of the t_{2g} bands possess even parity, while for X, Y, and Z points, two of the 4 empty bands have even parity and the other two bands possess odd parity. Thus, regardless the value of U, the summation of the number of empty t_{2g} states with odd parities at Γ, X, Y, and Z points is 6. On the other hand, the Coulomb interaction has a significant effect on the parities of the bands around the L points. This is shown in Table III, where the summation of the number of the odd states are 6 and 4 for U=1.5 and 0.5 eV, respectively. Therefore, for U=1.5 eV, we have $\theta = 0$, which corresponds to a normal insulator. However, for U=0.5 eV, we have $\theta = \pi$, which leads us to the axion insulator with novel magnetoelectric properties.

4

TABLE III: Calculated parities of states at Time Reversal Invariant Momenta (TRIMs) for $CaOs_2O_4$. Only 4 empty t_{2g} bands are shown in order of increasing energy. L_x denotes $2\pi/a(-0.5,0.5,0.5)$, L_y denotes $2\pi/a(0.5,-0.5,0.5)$, L_z denotes $2\pi/a(-0.5,0.5,0.5)$ and L denotes $2\pi/a(0.5,0.5,0.5)$.

	L_x	L_y	L_z	L
U=0.5 eV	++++	++++	++++	- - - -
U=1.5 eV	-+++	-+++	-+++	+ - - -

Topological insulators must be separated from trivial insulators by a semi–metallic state[23], with 3D Dirac/Weyl–like dispersion. To find the boundary between semi–metal and Axion insulator as well as between semi–metal and Mott insulator we perform calculations for a number of intermediate values of U. While the validity of the LDA+U scheme for semi–metallic states can be questioned in general, recent studies of Graphene [37] show a very good agreement between electronic structure theory and angle–resolved photoemission experiments. This hints that the mean field approach can be a good starting point for describing band crossings such as Dirac points or Weyl points considered in our work. Our calculations for U's varying from 1.0 to 1.3 eV show that there are 3D Weyl crossings close to $(0.02, x, 0.02)2\pi/a$ and its symmetry related points of the BZ, where the value of x changes with U. With both decreasing and increasing U, the Weyl points move and annihilate by meeting with each other, thus opening the energy gap and forming either the $\theta = \pi$ Axion insulator or normal insulator, respectively.

To summarize, our electronic phase diagram (see Fig. 3) for U <0.4 eV, predicts $CaOs_2O_4$ to be a metal; for 0.4< U <0.9 eV, an axion insulator; for 0.9< U <1.4 eV, a topological semi-metal metal; for U >1.4 eV, a Mott insulator. Note, as in the cubic pyrochlore iridates [23] symmetry dictates that the eight Weyl points realized in this systems are all exactly at the Fermi energy. To see the sensitivity of these results to the lattice parameters we perform calculations with increasing and decreasing the volume by 6%, as well as adjusting the internal coordinates and performing small changes in Os-O-Os bond angle. We confirm that while there are some little changes in calculated energy bands, our predictions on Axion insulator behavior are robust.

Replacing Ca by Sr, both the Os-O-Os bond angle and the bond length will change as shown in Table I. However, same as $CaOs_2O_4$, $SrOs_2O_4$ shows the same rich phase diagram as a function of U.

We finally study $BaOs_2O_4$ which has both the largest bond angle and bond length as shown in Table I. These differences significantly affect its band structure: the LDA+SO calculation with U=0 gives that at the Γ point the eight $J_{eff} = 1/2$ states have degeneracies 4-2-2 and not 2-4-2 as found in Ca and Sr cases. Note that this se-

FIG. 3: Sketch of the predicted phase diagram for spinel osmates.

quence of levels is the same as recently suggested by Pesin and Balents to realize topological insulating scenario in pyrochlore iridates [21]. Unfortunately, the bands crossing the Fermi level exist and cannot be removed by slight adjusting the lattice constant. Same with $CaOs_2O_4$ and $SrOs_2O_4$, considering the Coulomb interaction U will induce magnetism, but we do not find axion-insulator or Weyl–metal state for $BaOs_2O_4$ for any reasonable U.

To summarize, using density functional based electronic structure calculations, we have found that depending on the strength of the Coulomb correlation among the 5d orbitals several exotic electronic phases may be realized in Os based spinel compounds. In particular magnetic topological insulating phase (axion insulator) may be realized in $CaOs_2O_4$ and $SrOs_2O_4$ with large orbital magneto–electric parameter $\theta = \pi$. This research suggests that new functionalities such as controlling electrical[14] and optical [38] properties via magnetic textures, can be found in the new 5d spinel materials that we proposed.
