Backflow Transformations via Neural Networks for Quantum Many-Body Wave Functions

Di Luo and Bryan K. Clark Phys. Rev. Lett. **122**, 226401 — Published 4 June 2019 DOI: [10.1103/PhysRevLett.122.226401](http://dx.doi.org/10.1103/PhysRevLett.122.226401)

Backflow Transformations via Neural Networks for Quantum Many-Body Wave-Functions

Di Luo¹ and Bryan K. Clark¹

¹Institute for Condensed Matter Theory and Department of Physics, University of Illinois at Urbana-Champaign, IL 61801, USA

Obtaining an accurate ground state wave function is one of the great challenges in the quantum many-body problem. In this paper, we propose a new class of wave functions, neural network backflow (NNB). The backflow approach, pioneered originally by Feynman [\[1\]](#page-5-0), adds correlation to a mean-field ground state by transforming the single-particle orbitals in a configuration-dependent way. NNB uses a feed-forward neural network to learn the optimal transformation via variational Monte Carlo. NNB directly dresses a mean-field state, can be systematically improved and directly alters the sign structure of the wave-function. It generalizes the standard backflow[\[2\]](#page-5-1) which we show how to explicitly represent as a NNB. We benchmark the NNB on Hubbard models at intermediate doping finding that it significantly decreases the relative error, restores the symmetry of both observables and single-particle orbitals, and decreases the double-occupancy density. Finally, we illustrate interesting patterns in the weights and bias of the optimized neural network.

Introduction.—A key question in strongly correlated quantum systems is to obtain an approximation for the ground state wave function. This is especially important for Fermion systems in two or more dimensions where only approximate or exponentially costly methods for evaluating observables of quantum systems exist. Early attempts for writing down variational Fermion wave-functions, such as Slater determinants [\[3\]](#page-5-2) and BCS wave-functions[\[4\]](#page-5-3), focused on finding the ground state of a mean field Hamiltonian which best matched the interacting ground state. Since these early attempts more sophisticated wave-functions have been developed which dress these mean-field starting points including Slater-Jastrow [\[5,](#page-5-4) [6\]](#page-5-5), Slater-Jastrow-Backflow [\[1,](#page-5-0) [7\]](#page-5-6) and iterative backflow [\[8\]](#page-5-7) which has recently been described as a non-linear network [\[9\]](#page-5-8). These wave-functions have the advantage that the mean-field starting point can directly incorporate the basic physics of the problem.

Instead of starting from a dressed mean-field, many other classes of wave-functions are parameterized by a tuning parameter D which interpolates from a trivial state at small D to a universal wave-function spanning the entire Hilbert space at exponential D. Examples of such wave-functions include matrix-product states[\[10,](#page-5-9) [11\]](#page-5-10), other forms of tensor networks[\[11–](#page-5-10)[13\]](#page-5-11), Huse-Elser states[\[14–](#page-5-12)[16\]](#page-5-13), and string-bond states [\[17\]](#page-5-14). Recently, wave-functions based on neural network primitives, such as restricted Boltzmann machines (RBM) and feed forward neural network(FNN), have been introduced with similar universal properties [\[18–](#page-5-15)[42\]](#page-6-0): as the number of hidden neurons increases, the neural network state can represent all probability distribution although may require complex weights to represent the sign structure of Fermion wave-functions. A recent attempt to incorporate RBM into Fermion states by using the RBM as a more general Jastrow [\[23\]](#page-5-16) shows promise but was still restricted to the sign-structure of the underlying meanfield ansatz. Even though general neural networks could

alter the sign-structure, it may struggle with capturing the underlying mean-field physics both in terms of the number of neurons required as well as optimization.

Figure 1. Cartoon of (spin-up) neural network being used in this work for a^{NN} (other transformations are similar) with input shown for the configuration displayed of 4 electrons on 3 sites. Every layer is fully connected with arrows but only a fraction of them are shown for image clarity. The input layer is set by the configuration. Parameters b_i and w_{ij} are bias and weights to be optimized. The output layer is a $n_\text{up-electrons}\!\times\!n_\text{sites}$ (i.e $2\!\times\!3)$ matrix which will be the backflow transformation added to the single particle orbitals.

In this work, we propose a new class of wave-functions, the Neural Network Backflow (NNB), which dresses a mean-field wave-function, can make changes to the sign structure directly, and can be systematically improved by increasing the number of hidden neurons and is able to be made theoretically exact in the limit of enough neurons. To accomplish this we use a feed-forward neural network (FNN), not in the standard approach of returning a wave-function amplitude, but instead to transform the single particle orbitals in a configuration dependent way; these orbitals are then used in the mean-field wavefunction. Wave-functions with configuration-dependent orbitals are known as a backflow wave-function[\[1,](#page-5-0) [2,](#page-5-1) [7–](#page-5-6)

[9,](#page-5-8) [43](#page-6-1)[–55\]](#page-6-2).

Background.—Mean field theory - approximating the ground state of a quartic Hamiltonian by the ground state, ψ_{MF} , of a quadratic Hamiltonian - is a powerful first step to understanding correlated quantum systems. Various mean fields lead to different types of ground states including Slater determinants,

$$
\psi_{SD}(\mathbf{r}) = \det\left[M^{SD,\uparrow}\right] \det\left[M^{SD,\downarrow}\right];\tag{1}
$$

$$
M_{ik}^{SD,\sigma} = \phi_{k\sigma}(r_{i\sigma})
$$
\n⁽²⁾

and Bogoliubov de Gennes wave-functions,

 \mathbf{v}

$$
\psi_{BDG}(r) = \det[\Phi] \tag{3}
$$

$$
\Phi_{ij} = \sum_{k,l=1}^{N} \phi_{k\uparrow}(r_{i,\uparrow}) S_{kl} \phi_{l\downarrow}(r_{j,\downarrow}) \tag{4}
$$

where $\phi_{k\sigma}$ is the k'th single particle orbital and $r_{i,\sigma}$ is the position of the *i*'th particle of spin σ . Eq. [\(1\)](#page-2-0) only takes the occupied orbitals while Eq. [\(3\)](#page-2-1) is summed over both occupied and unoccupied orbitals.

Mean field states are uncorrelated by construction. The simplest way to capture correlation physics is through the introduction of a Jastrow giving $\psi_{\text{Jastrow}}(\mathbf{r}) = \exp[-U(\mathbf{r})] \psi_{MF}(\mathbf{r}),$ where $U(\mathbf{r})$ is an arbitrary function. In this work, we always use a charge Jastrow $U(r) = \frac{1}{2} \sum_{i,j} v_{ij} n_i n_j$, where n_i is the charge density, v_{ij} is the variational parameters. While Jastrow factors can introduce many-body correlations, they can't modify the mean-field's sign structure. One approach to add additional sign-structure modifying correlation is through a backflow correction $[2, 7-9, 43-55]$ $[2, 7-9, 43-55]$ $[2, 7-9, 43-55]$ $[2, 7-9, 43-55]$ $[2, 7-9, 43-55]$ which introduces correlations by having the single-particle orbitals act on a configuration-dependent quasi-particle position. On the lattice, the backflow approach instead uses a configuration-dependent mean-field [\[2,](#page-5-1) [44,](#page-6-3) [45,](#page-6-4) [47\]](#page-6-5) - i.e. the quadratic Hamiltonian or single-particle orbitals $\phi_{k,\sigma}^b(r_i; \mathbf{r})$ depend not only on the position r_i but on all other electron positions r; our NNB builds on top of this formulation of backflow.

Neural Network Backflow.—The NNB uses a FNN to modify the single particle orbitals for a spin σ ,

$$
\phi_{k\sigma}^b(r_{i,\sigma}; \mathbf{r}) = \phi_{k\sigma}(r_{i,\sigma}) + a_{ki,\sigma}^{NN}(\mathbf{r}) \tag{5}
$$

where each value of $a_{ij,\sigma}^{NN}$ is represented by an output neuron of the FNN. We use one neural net for each of $\sigma \in \{\uparrow,\downarrow\}.$ This is to be contrasted with the standard backflow[\[44\]](#page-6-3) parameterization,

$$
\phi_{k\sigma}^b(r_{i,\sigma}; \mathbf{r}) = \phi_{k\sigma} + \sum_j \eta_{ij,\sigma} \phi_{k\sigma}(r_{j,\sigma})
$$

$$
\eta_{ij,\sigma} = t D_i H_j \theta_{|i-j|,\sigma} \tag{6}
$$

with $D_i = n_{i,\uparrow} n_{i,\downarrow}, H_i = (1 - n_{i,\uparrow})(1 - n_{i,\downarrow}).$ $\theta_{1,\sigma}$ and $\theta_{2,\sigma}$ are the only non-zero variational parameters.

Interestingly, the backflow transformation of Eq. [\(6\)](#page-2-2), can be represented as a neural network for $a_{ij,\sigma}^{NN}(\boldsymbol{r})$ with three hidden layers and a linear number of neurons; an explicit construction will be given in the next section. This ensures that there exists a three layer neural network which is at least as good as the standard backflow transformation.

Figure 2. Top Left: Percentage relative error from the exact ground-state energy of Eq. [7](#page-4-0) ($E = -11.868[56]$ $E = -11.868[56]$) on 4×4 Hubbard model at $U/t=8$, n=0.875, for various classes of wavefunctions. The star is the variance extrapolation result of $\Psi_{\rm PN}$ (see Supplementary Material [\[57\]](#page-6-7) Sec. I). Top Right: Percentage relative energy error $(E_{exact} - E_{NNB})/E_{exact} * 100$ $\%$, as a function of $1/m$ for NNB. Statistical error bars are shown but smaller than the marker size. Bottom: Variance extrapolated energy per site for Hubbard model with $U/t=8$, n=0.875 with system size $L \times 4$ for $L = 4, 8, 12, 16$. The dash line is the DMRG energy per site $(-0.7659 \pm 4 \times 10^{-5})$ for system size $\infty \times 4$ (PBC, open) [\[58\]](#page-6-8).

We consider two NNB wave-functions, Ψ_{SN} and Ψ_{PN} , implemented on top of a Slater Determinant and BCS pairing wave-functions respectively. The neural nets used in these wave-functions are similar although Ψ_{SN} has outputs which only correspond to the occupied orbitals, while the outputs of Ψ_{PN} correspond to all the orbitals. In addition, for Ψ_{SN} there are only two neural nets (one for each of the spin-up and spin-down orbitals) while for Ψ_{PN} there is an additional neural net used to generate a system dependent $S_{kl}(\boldsymbol{r})$. This is implemented by letting $S_{kl}(\boldsymbol{r}) = S_{kl} + d_{kl}^{NN}(\boldsymbol{r})$, where $d_{kl}^{NN}(\boldsymbol{r})$ is represented by an FNN (in this work always fixed to 16 hidden neurons) that inputs the system configuration r and outputs the symmetric matrix correction d_{kl}^{NN} . Notice that Ψ_{PN} is

method	backflow transformation	mean field	variational functions
$\psi_{\rm S0}$		Eq. (1)	$\phi_{k\uparrow}(r_{i,\uparrow}), \phi_{k\downarrow}(r_{i,\downarrow}), v_{ij}$
$\Psi_{\rm SN}$	$\phi_{k\sigma}^b(r_{i,\sigma};\bm{r})=\phi_{k\sigma}(r_{i,\sigma})+a_{ki,\sigma}^{NN}(\bm{r})\ .$	Eq. (1)	$a_{ki,\sigma}^{NN}(\boldsymbol{r}),v_{ij}$
$\Psi_{\rm PB}$	$\phi_{k\sigma}^b(r_{i,\sigma};\mathbf{r}) = \phi_{k\sigma}(r_{i,\sigma}) + \theta_{1\sigma}\sum_i tD_iH_j\phi_{k\sigma}(r_{j,\sigma}) + \theta_{2\sigma}\sum_i tD_iH_j\phi_{k\sigma}(r_{j,\sigma})$	Eq. (3)	$\theta_{1\sigma}, \theta_{2\sigma}, S_{kl}, v_{ij}$
$\Psi_{\rm PN}$	$\phi_{k\sigma}^b(r_{i,\sigma};\bm{r})=\phi_{k\sigma}(r_{i,\sigma})+a_{ki,\sigma}^{NN}(\bm{r});\,S_{kl}(\bm{r})=S_{kl}+d_{kl}^{NN}(\bm{r})$	Eq. (3)	$a_{ki,\sigma}^{NN}(\boldsymbol{r}), d_{kl}^{NN}(\boldsymbol{r}), v_{ij}$

TABLE I. Wave Function Ansatzs

trivially a superset of Ψ_{SN} .

Although various architectures can be used, we adopt a three-layer fully-connected FNN for each of the functions $a_{ki,\sigma}^{NN}$ and d_{kl}^{NN} (see Fig. [1\)](#page-1-0). The input layer has 2N neurons with neuron i (neuron $i + N$) outputting 1 if there is spin up (spin down) on site i and -1 otherwise, where N is the total system size. The hidden layer contains mN hidden neurons for constant m with Rectifier Linear Units (ReLU) [\[59\]](#page-6-9) activation functions. The output layer then contains $O(N^2)$ neurons specifying the values of the respective functions. Gradients are computed in the standard way using variational Monte Carlo (see Supplementary Material [\[57\]](#page-6-7) Sec. II) which requires evaluating the derivative of the wave-function with respect to the weights and bias in the neural network. Derivatives for FNN are typically taken using back-propagation. Because the wave-function is a determinant of a matrix generated by the neural-network output, we evaluate this full derivative by envisioning this determinant as an additional final layer of the neural network and then performing back-propagation including this layer. This ensures the cost of computing all the derivatives is of the same order as the evaluation of the wave-function (see Supplementary Material [\[57\]](#page-6-7) Sec. III). Optimization is performed by stepping each parameter in the direction of the gradient with a random magnitude, which helps us avoid shallow local minima [\[60\]](#page-6-10), or by the RMSPROP method [\[61\]](#page-6-11).

Figure 3. Charge Density (Top) and Spin Density (Bottom) from Ψ_{PN} with 8 hidden neurons (left) and 128 hidden neurons (right) on 4×4 Hubbard model at U/t=8, n=0.875.

The computational complexity of the NNB implemented with a single layer of $O(mN)$ hidden neurons

scales as $O(mN^4)$ per sweep (i.e. after N electrons move) for forward and backward propagation and $O(N^4)$ per sweep for the evaluation of the mean-field determinant. This is similar to the scaling of standard backflow.

Explicit construction of standard backflow.—In this section, we provide an explicit construction which represents the standard backflow transformation in the form of Eq. [\(6\)](#page-2-2) written as a NNB.

In Eq. [\(6\)](#page-2-2), $\eta_{ij,\sigma}$ = $tD_iH_j\theta_{|i-j|,\sigma}$ = $t n_{i,\uparrow} n_{i,\downarrow} h_{j,\uparrow} h_{j,\downarrow} \theta_{|i-j|,\sigma}$, where $h_{j,\sigma} = 1 - n_{j,\sigma}$, $\theta_{1,\sigma}$ and $\theta_{2,\sigma}$ are the only non-zero variational parameters. We first demonstrate that $\eta_{ij,\sigma}$ can be presented by a two layer neural network with input layer as $(\sigma_1, ..., \sigma_N, \sigma_{N+1}, ..., \sigma_{2N})$ where $\sigma_i = 2n_{i,\uparrow} - 1$ and σ_{i+N} = $2n_{i,\downarrow}$ – 1. By construction, $n_{i,\sigma}$ and $h_{i,\sigma}$ take value of 0 or 1 so that $n_{i,\uparrow}n_{i,\downarrow}h_{j,\uparrow}h_{j,\downarrow}$ is 1 if and only if $n_{i,\uparrow} = n_{i,\downarrow} = h_{j,\uparrow} = h_{j,\downarrow} = 1$. Therefore, $t\theta_{|i-j|,\sigma}D_iH_j = t\theta_{|i-j|,\sigma}n_{i,\uparrow}n_{i,\downarrow}h_{j,\uparrow}h_{j,\downarrow}$ is equivalent to ReLU $[t\theta_{|i-j|,\sigma}(n_{i,\uparrow} + n_{i,\downarrow} + h_{j,\uparrow} + h_{j,\downarrow} - 3)],$ which is the same as ReLU $[t\theta_{|i-j|,\sigma}(\sigma_i/2 + \sigma_{i+N}/2 - \sigma_{i+N})]$ $\sigma_j/2 - \sigma_{j+N}/2 - 1$]. As a result, for each $\eta_{ij,\sigma}$, we associate it with a hidden neuron, such that the weights connecting it to $\sigma_i, \sigma_{i+N}, \sigma_j, \sigma_{j+N}$ are $t\theta_{|i-j|,\sigma}/2, t\theta_{|i-j|,\sigma}/2, -t\theta_{|i-j|,\sigma}/2, -t\theta_{|i-j|,\sigma}/2$ respectively, the bias is $-t\theta_{|i-j|,\sigma}$ and the activation function is ReLU. In general, for more complicated backflow [\[2,](#page-5-1) [45,](#page-6-4) [47\]](#page-6-5) with terms $n_{i,\sigma}h_{i,-\sigma}n_{j,-\sigma}h_{j,\sigma}$, $n_{i,\sigma}n_{i,-\sigma}n_{j,-\sigma}h_{j,\sigma}$ and $n_{i,\sigma}h_{i,-\sigma}h_{j,\sigma}h_{j,-\sigma}$, where σ is the spin index, we can use more hidden neurons and represent it in the same way.

After we have the neural network construction for the standard $\eta_{ij,\sigma}$, the term $a_{ki}^{NN} = \sum_j \eta_{ij,\sigma} \phi_{k\sigma}(r_{j,\sigma})$ in Eq. [\(5\)](#page-2-3) can be realized through an extra layer taking the outputs $\eta_{ij,\sigma}$ to a neuron representing a_{ki} where the weight is given by the single particle orbital values $\phi_{k\sigma}(r_{i,\sigma})$, there is no bias and the activation function is the identity. This construction shows that the standard backflow parameterization is thus a subset of our threelayer NNB.

Results.—We have benchmarked the quality of our NNB on a number of systems including Hubbard models at various sizes and doping (all at $U/t = 8$) as well as a frustrated magnet, the Heisenberg model on the Kagome lattice. In the main text we focus primarily on the Hubbard model at $n = 0.875$ (primarily on the 4×4 lattice) leaving the additional benchmarks as Supplementary Material [\[57\]](#page-6-7) Sec. IV., [\[62](#page-6-12)[–64\]](#page-6-13)) The Hubbard Hamiltonian

$$
H = -t\sum_{i\sigma} (c_{i\sigma}^{\dagger} c_{i+1\sigma} + h.c.) + \sum_{i} U n_{i\uparrow} n_{i\downarrow} \tag{7}
$$

where we use $U/t = 8$. We compare the results to an optimized unrestricted (i.e. different single particle-orbitals for spin-up and spin-down) Slater Determinant (Ψ_{SO}) as well as a backflow BDG wave function (Ψ_{PB}) which transforms single particle orbitals of each spin by Eq. [\(6\)](#page-2-2). The formulation and the variational parameters of each wave function ansatz are summarized in Table. [I.](#page-3-0) The parameters which aren't optimized, such as the initial set of orbitals $\{\phi_{k\sigma}(r_{i,\sigma})\}$ are obtained for $\Psi_{\rm PB}$ and $\Psi_{\rm SN}$ by optimizing a restricted Slater-Jastrow wave-function while $\Psi_{\rm PN}$ uses orbitals taken from the free hopping Hamiltonian (in practice the nature of the neural net allows for a direct change to the orbitals by altering the bias' on the final layer).

The relative error of the energy of NNB is 1.4% (and 0.66% after variance extrapolation (see Supplementary Material [\[57\]](#page-6-7) Sec. I) which is significantly better then the standard wave-functions (see Fig. [2\(](#page-2-4)left)). We examine the effect of the number of hidden neurons mN (see Fig. [2\(](#page-2-4)right)). We find that at small hidden neuron number, Ψ_{PN} is much better than Ψ_{SN} but this advantage eventually largely disappears at large neuron number suggesting that a backflow parameterized with a small neural networks can compensate for the missing pairing in a Slater-determinant. Surprisingly in the regime we've probed both NNB have energies linear with respect to $1/m$ in spite of the fact that in the $m \to \infty$ limit, they both must become exact as the FNN could simply put the exact amplitude $\Psi(R)$ on one element of the diagonal [\[65\]](#page-6-14), one on the rest of the diagonal and zero everywhere else.

Figure 4. Spin-up (top) and spin-down (bottom) single particle orbital(s.p.o) for Ψ_{S0} (left) and Ψ_{SN} (right) with 256 hidden neurons on 4×4 Hubbard model at U/t=8, n=0.875, where the s.p.o are evaluated at the (1d-reshaped) spinconfiguration shown. For the s.p.o, row is orbital index and the column is position index.

In addition, we have studied the NNB at $4 \times L$ for $L = \{4, 8, 12, 16\}$ comparing against the DMRG energy

(PBC,open) for the $4 \times \infty$ system of $-0.7659 \pm 4 \times 10^{-5}$ per site [\[58\]](#page-6-8). We find our result very comparable (see Fig. [2](#page-2-4) (bottom)) to the DMRG result, especially for system sizes which are commensurate with wave-length 8 stripes[\[58\]](#page-6-8).

We also investigate how the neural network backflow wave function affects the observables of our system. We see the expectation of double occupancy decreases as $1/m$ (see Supplementary Material [\[57\]](#page-6-7) Sec. I) and the spin and charge densities become significantly more symmetric as the number of hidden neurons increases (see Fig. [3\)](#page-3-1).

To understand the role of neural network in backflow transformation, we investigate how the neural network backflow transformation modify the orbitals. In Fig. [4](#page-4-1) (right), we notice although the backflow transformation on spin up orbitals and spin down orbitals are performed by two different neural networks, they produce similar backflow transformed orbitals and roughly preserves the symmetry of spin up and spin down for a given configuration. This is different from the optimized unrestricted Slater Determinant Ψ_{SO} , which breaks the spin up and spin down symmetry significantly (see Fig. [4](#page-4-1) (Left)).

One feature of using a NNB is the ability to alter the sign-structure of the wave-function. Here we consider the amount the sign changes between Ψ_{SN} with 16 hidden neurons and Ψ_{SO} by evaluating the integral

$$
\frac{\int |\Psi_{\text{SO}}(x)|^2 \text{sgn}(\Psi_{\text{SN}}(x)) \text{sgn}(\Psi_{\text{SO}}(x)) dx}{\int |\Psi_{\text{SO}}(x)|^2 dx}
$$
(8)

which is approximately 0.815 giving a 9% difference between the signs.

Furthermore, we open up the Ψ_{SN} neural network for $m = 8$ and analyze the weight between the input layer and the hidden layer, which represents the features that the neural network learns from input. In Fig. [5,](#page-5-17) we plot these weights for both the spin-up and spin-down neural networks. Interestingly the spin-up neural network primarily has large weights connected to the spin-down configurations while the spin-down neural network primarily has large weights connected to the spin-up configurations. This allows the neural network to introduce correlation between spin-up and spin-down configurations. Another observation is that more neurons tend to take large weight in negative bias, and small weight in positive bias.

Conclusion.—In this paper, we utilize the generality of artificial neural networks and the physical insight from backflow to develop a new class of wave function ansatz, the neural network backflow wave function, for strongly correlated Fermion systems on lattice. It achieves good performance for Hubbard model at nontrivial filling. We also show improvement on a kagome Heisenberg model in the supplement. While this work has focused on Fermion system on the lattice, the NNB is straightforward to generalize to frustrated spin systems as well as the continuum. In the latter case, the input could be represented as a lexicographically ordered set of particle locations. Our work provides a new approach toward combining machine learning methodology with dressed mean-field variational wave-functions which allows us to take simultaneous advantage of their respective strengths.

Figure 5. Weights between the input layer and hidden layer for $\Psi_{\rm SN}$ with 256 hidden neurons for the spin-up (left) and spin-down (right) neural networks on 4×4 Hubbard model at $U/t=8$, n=0.875. Hidden neurons are ordered by their bias and shown are neurons 1-32 (top), 96-128 (middle) and 224-256 (bottom).
