(Dated: December 7, 2017)

Recent experimental work has revealed that the unusually strong, isotropic structural negative thermal expansion in cubic perovskite ionic insulator ScF3 occurs in excited states above a ground state tuned very near a structural quantum phase transition, posing a question of fundamental interest as to whether this special circumstance is related to the anomalous behavior. To test this hypothesis, we report an elastic and inelastic X-ray scattering study of a second system Hg2I2 also tuned near a structural quantum phase transition while retaining stoichiometric composition and high crystallinity. We find similar behavior and significant negative thermal expansion below 100K for dimensions along the body-centered-tetragonal c axis, bolstering the connection between negative thermal expansion and zero temperature structural transitions. We identify the common traits between these systems and propose a set of materials design principles that can guide discovery of new materials exhibiting negative thermal expansion.

Negative thermal expansion (NTE) is an emerging area of material behavior discussed in chemistry, engineering, and physics which challenges conventional notions of lattice dynamics. Two routes to realizing NTE have been realized: one recipe is via a broadened phase transition from some high-temperature phase to a higher-volume, lower temperature phase. Treatment with quenched disorder can smear the transition and achieve a gradual and tunable NTE evolution of lattice parameters. Examples of this type of NTE are found in InVar1, anti-perovskites2,3, ruthenates4, and charge-transfer insulators5,6. In contrast, a second type of NTE is realized from intrinsic dynamical origins, also referred to as structural NTE (SNTE)7, which is not obviously resultant from phase competition and does not require quenched disorder but seems to arise from intrinsic geometrical modes with tendencies to draw in the lattice dimensions when thermally activated. Unlike the broadened phase transition type, SNTE appears in a wide variety of lattice systems8,9 without necessarily constraining the magnetic or electronic phase diagram. This freedom allows one to envisage new multifunctional materials with diverse mechanical, spin, orbital, thermal, electronic, superconducting, and more exotic order coexisting with NTE, potentially enabling the benefits of strain control to enable new types of order.

ScF3 is prominent among SNTE systems, forming in the so-called “open” perovskite (ReO3-type) structure with a small, four-atom unit cell and cubic symmetry at all temperatures below the high melting point of 1800K (Fig 1a).10-16. The linear coefficient of thermal expansion (CTE) of this material is isotropic, strongly negative, and persistent over 1000K temperature window10. Combined computational and inelastic scattering work11 has described the configurational potential for R point distortions as having a nearly quartic form at small displacement, presenting an interesting limit of lattice dynamics. Further inelastic scattering investigations on single crystals aimed at exploring the consequences of this unusual situation discovered an incipient soft-mode instability12 implying the development of a structural instability with a small extrapolated critical temperature \( T_c < 0 \). This result implies that while similar compounds like TiF3 realize a cubic-to-rhombohedral structural phase transition, the transition is never realized in ScF3, except under an extremely small <1kbar hydrostatic pressure at cryogenic temperatures. These special circumstances are contextualized in Figure 1a, which shows the global structural phase diagram of 3d transition metal trifluorides BF3 as a function of the B\(^{+3}\) ionic radius, \( r_B \). The occurrence of the endpoint of a structural phase boundary so near the ground state of a stoichiometric compound is extremely rare, as is the pronounced SNTE property of ScF3. The confluence of these unusual circumstances raises the broad question of whether SNTE can arise as unusual behavior above structural quantum phase transitions (SQPTs) associated with transition shifts of linking units between volume-defining vertices. To directly address this issue, we have explored the thermal expansion behavior and lattice fluctuation spectra in optical/detector quality single crystals of a second stoichiometric SQPT material Hg2I2, known colloquially as protiodide17.

Figure 1b summarizes the known structural phase diagram of the mercuric halides Hg2X2 (X=Cl, Br, I) as a function of the X\(^-\) ionic radius \( r_X \). The high symmetry structure in this case is body-centered tetragonal (BCT; Fig 1e) and can be described as a dense packing
of X-Hg-X linear molecules oriented along the tetragonal c axis\(^{20}\). The basic structural unit that defines the high-temperature unit cell is an elongated square dipyramid (ESD) formed as a cage with parts of 10 X\(^{-}\) ions surrounding a Hg dimer oriented along c, shown in Figure 1b inset and Figure 4b. The structural transition to the orthorhombic phase can be described as a freezing of the Hg dimer transverse fluctuation in a staggered pattern (Fig. 1f) at the \(X\) point of the BCT Brillouin zone.

Single crystals of Hg$_2$I$_2$ and Hg$_2$Br$_2$ were prepared from purified materials using physical vapor deposition as previously reported\(^{17}\). Diffraction and inelastic X-ray scattering (IXS) data were collected using the HERIX spectrometer in sector 30 of the Advanced Photon Source, Argonne National Laboratory. Figure 2 shows the lattice parameters of ScF$_3$\(^{10}\) and Hg$_2$I$_2$ along with data from their nearest realized structural transitions in TiF$_3$\(^{18}\) and Hg$_2$Br$_2$, respectively, for comparison. In the case of TiF$_3$ (Fig 2a), the cubic-to-rhombohedral transition has profound effects on the lattice dimensions, showing a signature step of a first order transition and subsequent continuous order parameter development, shrinking ~3% between the structural transition temperature \(T_c\) and base temperature\(^{21}\). The hexagonal c axis on the other hand displays SNTE similar in magnitude to the negative CTE observed along the cubic a axis of ScF$_3$ in the same temperature range. The lattice expansion of the realized transition in Hg$_2$Br$_2$ bears remarkable resemblance, with a significant reduction in tetragonal c axis lattice parameter below the transition, changing 4.5% between 150K and base temperature. The transition appears to be nearly continuous, consistent with prior work\(^{22}\). The c axis of Hg$_2$I$_2$ however shows a strongly negative CTE below 100K shown in Figure 2d, reaching a significant low-temperature value of -5ppm/K. While negative values of the c-axis compressibility have been noted in mercurous halides\(^{23}\), SNTE in Hg$_2$I$_2$ has not been reported to our knowledge.

The similarities to the fluorides are striking - both real-
ized transitions TiF$_3$ and Hg$_2$Br$_3$ show a strong positive CTE below their respective transitions while the systems tuned near SQPTs show SNTE in high symmetry directions aligned with a linkage undergoing strong transverse fluctuations at the lowest temperatures. Beyond the phase diagram and structural motifs, we note other gross similarities between these two material classes: they are ionic insulators with no reported magnetism or free carriers and retain high symmetry structures at all temperatures below their respective melting temperatures. Furthermore, both systems are driven to lower symmetry phases at modest pressure and ambient temperature (ScF$_3$ cubic-to-rhombohedral at $p_c$=7kbar and 300K$^{10}$, Hg$_2$I$_2$ body-center-tetragonal-to-orthorhombic at $p_c$=9kbar and 300K$^{24}$) or very low pressure at cryogenic temperatures (estimated $p_c$~1kbar for both systems at 4K$^{10,25}$). We note also analogous structural motifs: the bridging F ion in ScF$_3$, which occurs in all three spatial directions and the bridging Hg dimer, which is oriented along the c axis in the mercures halides.

Figs 2c,d show remarkable similarities in the functional form of the CTE of Hg$_2$I$_2$ and ScF$_3$, which strengthen significantly at low temperature, implying the relevant lattice modes lie at extremely low energy. Apart from exceptional cases$^{26,27}$, the influence of higher-energy bond-stretch excitations are expected to provide positive thermal expansion influences which generically compete with SNTE due to the short-range hardening and long-range softening of central force interionic potentials (Fig. 2f)$^{28,29}$, which explains the overwhelming prevalence of positive thermal expansion in materials at ambient temperature. For Hg$_2$I$_2$, the magnitude of the c-CTE (~5ppm/K) is about one third of the maximum a-CTE in ScF$_3$ (-14ppm/K) and the range of thermal persistence is also reduced about 10-fold. This suppression can be partially explained by the much larger mass in the iodide case (ScF$_3$ density 2.53g/cm$^3$; Hg$_2$I$_2$ density 7.7g/cm$^3$), which significantly reduces the phonon bandwidth (~140meV in ScF$_3$$^{15}$ and ~25meV in Hg$_2$I$_2$$^{24}$) and activation energy for bond-stretch dynamics which compete with and ultimately overtake the SNTE effect. We point out further that quenched disorder is known to compete with SNTE$^{30}$, and while we have restricted our attention to pure stoichiometric systems, the halide system is likely more disordered than the fluoride based on comparison of the rocking curve width (0.002$^\circ$ for ScF$_3$ and 0.13$^\circ$ for Hg$_2$I$_2$; see Supplemental Materials$^{42}$). A recent study of a SQPT achieved through chemical substitution shows prominent elastic and thermodynamic anomalies near the SQPT in solid solution LaCu$_6$-$x$Au$_x$$^{31}$ but does not report SNTE near the critical composition. In contrast, both ScF$_3$ and Hg$_2$I$_2$ lie very close to the critical endpoint of a structural phase boundary without the additional detrimental effects of quenched disorder.

Figure 3 provides an experimental basis to demonstrate proximities to SQPTs in ScF$_3$ and Hg$_2$I$_2$, showing inelastic X-ray scattering spectra at the momentum points corresponding to the soft mode instabilities. The trifluoride low-temperature phase can be described as a staggered tilt of octahedra around the 111 axis (Figure 1f). This fluctuation has the $(\pi,\pi,\pi)$ spatial texture of the R point in the simple cubic Brillouin zone, shown in Figure 3a. Also shown is a surface plot of the dynamical structure factor $S(R,\omega)$ obtained using IXS$^{12}$. At high temperature, a Stokes and anti-Stokes mode at low frequency of 3.4 meV softens considerably, approaching an extrapolated transition temperature $T_c$~39 K, as shown in Figure 3c. This singular point in the response function is suggestive of a flattening of the free energy landscape in an approach to an unrealized structural phase transition and strongly supports our identification of ScF$_3$ as near a SQPT.

In the halide case, starting from the BCT phase, the relevant distortion to the low-temperature orthorhombic phase is a staggered shift of the Hg-Hg dimer from the ESD central axis in the 110 direction of the basal plane (Figure 1f) and the structural transition then corresponds to condensation of the transverse acoustic wave at the X point of the BCT Brillouin zone$^{22,32,33}$. **FIG. 3:** (a) Dynamical structure factor for ScF$_3$ collected using inelastic X-ray scattering at the (2.5,3.5,0.5) reciprocal vector, corresponding to the R point of the simple cubic Brillouin zone, shown as an inset. (b) Dynamical structure factor for Hg$_2$I$_2$ collected using inelastic X-ray scattering at the (2.5,3.5,0) reciprocal vector, corresponding to the X point of the body-centered tetragonal Brillouin zone, shown as an inset. (c) Soft mode frequency squared determined from fits to the data in (a), showing the incipient ferroelastic state underlies the SNTE effect in ScF$_3$. (d) Soft mode frequency squared determined from fits to the data in (b), showing the incipient ferroelastic state also underlies the SNTE effect in Hg$_2$I$_2$.
ure 3b,d shows the evolution of $S(X, \omega)$ with temperature and an avoided condensation of a soft mode at the $X$ point of the body-centered tetragonal Brillouin zone in Hg$_2$I$_2$. $S(X, \omega)$ also shows Stokes/anti-Stokes mode pairs that imply a putative transition at $T_c \sim 23$ K. This is fully consistent with previous studies on single crystals using energy-integrated diffuse X-ray scattering showing $T_c \sim 20$ K$^{34}$. We explore more detailed analysis of the influences driving these incipient structural transitions in each case below.

For the realized structural transitions in the mercurous halides $X=Cl$,Br$^{23,34}$, $T_c > 0$ and the $T=0$ energy landscape consists of four minima corresponding to the possible saturated shifts of the Hg dimers (Fig 4d). For larger ionic radius $X=I$, these minima flatten and coalesce to the central axis, as no symmetry breaking is observed. The flattening of the energetic landscape however induces strong temperature-dependent fluctuations of the staggered shift, as is observed experimentally from X-ray diffraction data as large transverse dimensions of the Hg thermal ellipsoids, approaching $2\sqrt{U_{11}}=0.38\AA$ at $T=150$ K for Hg$_2$I$_2$.$^{35}$

To gain further insight into the origin of the avoided transition in Hg$_2$I$_2$, we analyze trends among the bond lengths of the ESD, which is not regular, but rather compressed (Fig 1b inset), defined by X-X bond lengths of the three types of the mercurous halides with purple spheres representing X$^-$ and silver spheres representing Hg$^+$ ions. $B^{+3}$ or X$^-$ ionic radius increases from left to right in (a) and (b) respectively. Overlayed lines show the ESD of Figure 1b inset, where solid lines lie in the plane of the page and dashed lines show bonds that protrude out of the plane. (c,d) Comparison of the observed bond distances and expectations based on hard sphere packing (dashed lines) for (c) transition metal trifluorides in the cubic phase$^{49}$ and (d) mercurous halides in the BCT phase. Symbols in (d) are from corresponding references: triangles$^{38}$, squares$^{39}$, pentagons$^{37}$, hexagons$^{36}$, septagons$^{50}$, and circles$^{39}$.

![FIG. 4: (a) Development of the structures of the transition metal trifluorides, with purple spheres representing F$^-$ and silver spheres representing B$^{+3}$ ions. (b) Development of the structures of the mercurous halides with purple spheres representing X$^-$ and silver spheres representing Hg$^+$ ions. B$^{+3}$ or X$^-$ ionic radius increases from left to right in (a) and (b) respectively. Overlayed lines show the ESD of Figure 1b inset, where solid lines lie in the plane of the page and dashed lines show bonds that protrude out of the plane. (c,d) Comparison of the observed bond distances and expectations based on hard sphere packing (dashed lines) for (c) transition metal trifluorides in the cubic phase and (d) mercurous halides in the BCT phase. In a similar set of considerations, we analyze the evolution of the basic trifluoride octahedral subunit with $r_B$, used as a baseline for comparison of relative size effects. Figure 4a shows that to a good approximation, the unit cell dimension $F$-B-$F$ ionic distance ($a$ lattice parameter) trends with $r_F + r_B$ while the nearest $F$-$F$ distance grows to values significantly in excess of $2r_F$. We note further that for $r_B > 0.75r_A$ in the rare-earth class and beyond, trifluorides take on other crystalline structures with B site coordination larger than $n=6$ in the orthorhombic tysonite ($n=8$), and hexagonal ($n=9$) structures. Together, these observations suggest an effective reduction of the overall stiffness of $\text{BF}_6$ octahedron for large B ions through reduced interaction of the anions situated at the octahedral vertices. In this case, a large number of SSSs are removed as the octahedral unit loses integrity with increasing $r_B$. Notably, fluctuations of the $F^-$ position transverse to the B-$F$-$B$ bond are very large in ScF$_3$, approaching $2\sqrt{U_{35}}=0.24A^{11,14,15}$ at $T=150$ K, consistent with this picture. In contrast to the mechanism in the mercuroic iodide, we expect that the onset of pliancy of octahedral molecules stabilizes the cubic phase, as many states are available with the average cubic structure. This situation is also manifest in the high melting point of ScF$_3$, where the high entropy of transverse bond fluctuation competes with the fluid phase as high as 1800K.

We note that incipient lattice instabilities and broadly systems tuned near SQPTs have recently attracted renewed interest$^{52}$ in light of their use to develop a 50% increase$^{53}$ in superconducting transition temperature of Nb-doped SrTiO$_3$ in an exceptional limit of the strong coupling theory$^{54}$, while the recent observation of electronic coupling to a substrate phonon in FeSe films raises questions regarding the possible role of substrate lattice fluctuations in stabilizing film superconductivity$^{55}$. The common appearance of incipient soft modes also in SNTE materials potentially opens promising areas for future work combining SNTE and superconductivity to realize new emergent phases enabled by extremal strain conditions. Our results here suggest renewed importance of spectroscopic studies of known high-symmetry NTE materials such as ZrW$_2$O$_8$$^{36,57}$, Zn(CN)$_2$$^{38,59}$, and Ag$_3$(Co(CN)$_6$)$_2$$^{60}$. The transition metal trifluoride and mercuroic halide materials bear strong similarities besides the unusual strengthening of the SNTE effect at low temperature. In both cases, molecular units form a high-symmetry structure whose bonds are on average straight and are situated so as to define the linear dimensions of the crystal, a in ScF$_3$ and c in Hg$_3$I$_2$. On approach to zero temperature, high-energy bond-stretch excitations become frozen out quickly according to the Bose factor, while the soft mode angular fluctuations reduce more gradually due to the observed $\omega \propto \sqrt{T}$ dependence. These competing influences lead to trend of NTE strengthening at the lowest temperatures and conventional expansion at elevated temperatures and the soft mode is crucial to boost the weak NTE influence. From this point of view, ScF$_3$ has extremely strong and thermally-persistent NTE behavior due both to the stiff bond-stretch, three dimensional lattice system, and proximity to the SQPT. The incipient nature of the transition is vital to this condition to avoid a staggered strain symmetry breaking which disrupts the coupling of angle to dimension. We generalize this understanding in a proposal that candidate SNTE materials may be identified in systems which have (i) structural instability associated with a transverse linkage shift between-volume-defining vertices, (ii) soft modes and large fluctuations of the near the SQPT, (iii) low quenched disorder and stoichiometric composition, and (iv) relatively stiff bond-stretch excitations.
